1.0 INTRODUCTION

1.1 Background and Purpose

The Clean Air Act (CAA) established the requirements to quantify and report air pollutant emissions from mobile and stationary sources. The purpose of the CAA is to protect public health by addressing the risks posed by certain air pollutants. The United States Environmental Protection Agency (EPA) has established National Ambient Air Quality Standards (NAAQS) which require facility managers to always know if they comply with air regulations. The EPA regulates most mobile sources of air pollution (e.g., automobiles at 40 Code of Federal Regulations (CFR) 85-86, and airplanes at 40 CFR 87, etc.) under Title II of the CAA. Performance standards issued by the EPA limit the emission of certain pollutants from these sources. Fuel-related requirements under Title II at 40 CFR 79-80 are designed to further reduce emissions from mobile sources.

For an installation, such as an Air Force base, the total air pollutant emissions are determined by conducting an Air Emissions Inventory (AEI). An air emissions inventory is the sum of all air pollutant emissions from each source over a stated period of time, typically one year. Air quality regulations vary from region to region, and the local regulatory agency should be consulted prior to conducting an AEI since some local agencies have specific data reporting requirements and/or protocols that the installation must obey. An AEI must be periodically updated as required by federal, state, and local regulations. **Each installation must calculate and record all collected data in the Air Program Information Management System (APIMS).** AEIs must be updated any time there is a change in mission, equipment, and/or operating procedures that result in a substantial change (approximately 5%) in air emissions.

The purpose of this guide is to provide authoritative documentation for National Environmental Policy Act (NEPA) and General Conformity analyses, *not* for conducting AEIs comprised solely of mobile emissions sources (Mobile AEIs). Mobile source AEIs are primarily conducted to provide data during the development of State Implementation Plan (SIP) budgets. However, since the SIP only accounts for criteria and precursor pollutants, it is unnecessary to calculate emissions for other pollutants though emission factors (EFs) may be provided in this guide. It is still imperative that the Department of the Air Force (DAF) adopts a uniform approach to calculating air pollutant emissions for the most common mobile sources found at DAF installations. This guide serves this purpose by being the DAF's single authoritative resource for mobile source emission estimating algorithms and EFs; no other algorithms or EFs shall be used unless mandated by a legally enforceable regulatory requirement (e.g., permit stipulates) or approved by Air Force Civil Engineer Center/Environmental Quality Technical Support Branch (AFCEC/CZTQ) that is reviewed on a case-by-case basis.

Any questions concerning this guide, or requests for additional information pertaining to Air Force AEIs, should be directed to the Air Quality Subject Matter Expert; AFCEC Compliance Technical Support Branch located at, 2261 Hughes Ave., Ste 155, JBSA Lackland, Texas 78236-9853.

1.2 Mobile Sources

This guide only addresses mobile emission sources typically found on DAF installations. A mobile source is defined as any type of non-stationary equipment that may emit an air pollutant subject to regulation by the CAA. These mobile sources include aircraft and aircraft support equipment, on-road vehicles, and non-road engines. The description of stationary sources contributing to air emissions and the methods for calculating these emissions may be found in the *Air Emissions Guide for Air Force Stationary Sources*. It should be noted that certain districts may classify non-road engines as a stationary source rather than a mobile source, therefore it is important to consult with the local air quality district for clarification as needed.

1.3 Air Emissions Inventories (AEIs)

AFMAN 32-7002, Environmental Compliance and Pollution Prevention, states the following regarding AEIs:

4.5.1. Air Emissions Inventory (AEI). The Installation Environmental Element must prepare and periodically update an AEI, using APIMS, for all installation stationary air emission sources in accordance with applicable state or local requirements promulgated per 40 CFR Part 51, Subpart A and current AF AEI guidance from AFCEC/CZ. **(T-0)**.

4.5.1.1. Regulatory-required stationary AEIs are completed at the frequency specified by federal, state, and local regulations.

4.5.1.2. Comprehensive stationary AEIs (applicable to all installations, including overseas) include all emissions sources (i.e., both permitted and non-permitted sources). The Installation Environmental Element will annually review/validate APIMS to ensure currency of the AEI (i.e., sources and consumption data is representative of the current base conditions). **(T-1)**. A comprehensive review of all sources and associated consumption data for the AEI will be conducted at least every three years (five years for overseas and remotely located facilities) to accurately reflect current emissions. **(T-1)**.

4.5.1.3. Stationary source AEIs include all criteria pollutants, Hazardous Air Pollutants, and greenhouse gases and reflect the installation's current actual and PTE emissions. Annual regulatory emissions reports, a subset of the comprehensive AEI, are provided to federal, state, and local (including Metropolitan Planning Organization or other regional) regulatory agencies as required. Greenhouse gas reporting mandated by E.O. 13834, is accomplished by SAF/IEE in conjunction with the Annual Energy Management and Resilience reporting process.

4.5.1.4. For installations that exceed the greenhouse gas reporting threshold, the Installation Environmental Element shall accomplish greenhouse gas reporting mandated by 40 CFR Part 98. **(T-0)**. Recommend other installations within 10% of the greenhouse gas reporting threshold accomplish greenhouse gas estimates in accordance with the nondirective Guide to the Mandatory Greenhouse Gas Reporting Rule and Greenhouse Gas Tailoring Rule, issued by AFCEC/CZ. Results will be reported to AFCEC/CZ via APIMS. **(T-1)**. Greenhouse gas reporting mandated by E.O. 13834 is accomplished by SAF/IEE in conjunction with the Annual Energy Management and Resilience reporting processes.

This guide describes the recommended methodologies for calculating actual emissions (i.e., from existing sources) and projected emissions (i.e., from projected federal actions). AEIs of these emissions may be required in order to fulfill a requirement for reporting for a certain period and frequency (e.g., reported for the previous calendar year on an annual basis). AEIs are usually accomplished to meet one or more regulatory requirement(s). The most common regulatory requirements for conducting a mobile source AEI are summarized below.

1.3.1 Title II – Emission Standards for Moving Sources

The EPA regulates most mobile sources of air pollution under Title II of the CAA which sets the standards for motor vehicle and aircraft emissions. Under Title II, the standards are set to control emissions that may endanger public health and welfare. Title II goes on to state that for motor vehicles, it is the manufacturer's responsibility to establish and perform tests which evaluate the emissions from the device. All testing results are to be maintained/documented and must be made available to any agent of the enforcement authority when requested. Similarly, Title II of the CAA states that the Secretary of Transportation will work to ensure that all aircraft emissions comply with the established air pollution standards.

1.3.2 Implementation Plans

As specified under Section 110 of the Clean Air Act, all States are required to submit a SIP to the EPA which provides for the protection and enhancement of air quality to promote public health and welfare. The SIP provides details for implementation, maintenance, and enforcement of the National Ambient Air Quality Standards (NAAQS). For areas in the State that are classified as nonattainment with any NAAQS, the SIP must provide strategies for obtaining attainment. For areas in the State that are already classified as being in attainment, the SIP must provide strategies for maintaining attainment status. All SIPs and SIP revisions must be reviewed and approved by the EPA. If the EPA considers a SIP to be incomplete or inadequate, they may issue their own plan called a Federal Implementation Plan (FIP).

Historically, most control strategies incorporated into implementation plans have targeted stationary sources. However, due to the constant increase in the number of air pollution sources, the issuance of new ambient air quality standards, and the fact that mobile sources emit most of the overall emissions, more control strategies targeting mobile sources are now being incorporated into implementation plans. Since AEIs are typically used to assess the effect of control strategies, an increase in the number of control strategies pertaining to mobile sources will result in an increase in requirements to conduct mobile source AEIs.

1.3.3 General Conformity

Section 176(c) of the CAA prohibits federal activities from taking various actions in nonattainment or maintenance areas unless they first demonstrate conformance with their respective State Implementation Plan (SIP). “A Federal Agency must make a determination that a Federal action conforms to the applicable implementation plan in accordance with the requirements of this Subpart **before the action is taken**” (40 CFR 93.150(b)). A conformity review is a multi-step process used to determine and document whether a proposed action meets the conformity rule. There are two main components to this process: an **applicability analysis** first establishes if a full-scale conformity determination is required and, if it is, a **conformity determination** assesses whether the action conforms to the SIP. The general conformity program requires all federal actions in nonattainment and maintenance areas to comply with the appropriate SIP. An emissions inventory is usually required as part of the conformity determination to identify/quantify air emissions from the proposed federal actions.

1.3.4 National Environmental Policy Act (NEPA)

The National Environmental Policy Act (NEPA) requires Federal agencies to evaluate the environmental impacts associated with major actions that they either fund, support, permit, or implement. There are as many as three levels of analysis:

- **Categorical Exclusion Determination** – A proposed action may be categorically excluded from a detailed environmental analysis if the action meets certain criteria which a previous agency has determined to have no significant environmental impact.
- **Environmental Assessment (EA)** – An EA is an evaluation to determine if a proposed action that was not categorically excluded would significantly affect the environment. If the effects are not significant, the agency issues a Finding of No Significant Impact (FONSI). If the EA concludes the action results in a significant environmental impact, an Environmental Impact Statement must be prepared.
- **Environmental Impact Statement (EIS)** – An EIS is a detailed evaluation of the proposed action, and its alternatives. A draft EIS is filed with the EPA and the EPA publishes a “Notice of Availability” in the Federal Register. Publication of the “Notice of Availability” begins a 45-day public comment period and mandatory 30-day waiting period before the agency can decide on the proposed action.

1.3.5 Other Inventory Uses

Complying with environmental regulations is not the only reason AEIs are conducted. An AEI can be a useful tool in helping industrial facilities implement various environmental programs. The most common program that may involve mobile source emission inventories is summarized below.

1.3.5.1 Pollution Prevention (P2) Opportunities

An AEI can be a useful tool in identifying air related P2 opportunities on military installations. The inventory identifies the types of air pollution sources on base and their accompanying emissions. Due to the large amount of emissions produced from mobile sources, as well as emerging technologies/strategies for reducing mobile source emissions, implementing P2 opportunities for mobile sources is becoming more commonplace.

1.4 Emissions Inventory Methodologies

When conducting an AEI, the quantity of regulated pollutants emitted from all emission sources located on an Air Force installation (except those sources that are specifically exempt) must be determined. Several methods can be used to quantify air pollutants from emission sources. Data from source-specific emission tests or continuous emission monitoring systems (CEMS) are usually preferred for estimating a source’s emissions. The CEMS data provides the best representation of the tested source’s emissions. However, source-specific emission tests or continuous emission monitoring of mobile sources at a large installation, such as an Air Force

base, may be impractical. Therefore, EFs and/or mass balance calculations are frequently the best or only method available for estimating emissions, despite their limitations.

An EF is a representative value that attempts to relate the quantity of a pollutant emitted with an activity. These factors are usually expressed as the mass of pollutant released per a unit weight, volume, distance, or duration of the activity emitting the pollutant (e.g., pounds of a pollutant emitted per 1,000 pounds of fuel burned). In most cases, these factors are simply an average of all available data of acceptable quality and are generally assumed to be representative of long-term averages for all processes in the source category (i.e., a population average).

The general equation for emission estimation using an EF is:

$$E = A \times EF \times N$$

Equation 1-1

Where,

- E*** = Total emissions
- A*** = Activity rate
- EF*** = Emission factor
- N*** = Number of engines/aircraft/equipment

For some sources, a mass balance approach may provide a better, more accurate estimate of emissions than emission tests would. In general, mass balances are appropriate for use in situations where a high percentage of material is lost to the atmosphere (e.g., sulfur in fuel). As the term implies, all the materials going into and coming out of the process must be considered to allow an emission estimation to be credible.

1.5 Pollutants

Although there are several types (groups/classes) of federal and state regulated pollutants which may be addressed in an AEI, this guide focuses on criteria pollutants, Hazardous Air Pollutants (HAPs), Volatile Organic Compounds (VOCs), and Greenhouse Gases (GHGs).

1.5.1 Criteria Pollutants

In 1971, the EPA established National Ambient Air Quality Standards (NAAQS) for six pollutants which are termed criteria pollutants. These include particulate matter (PM), ozone (O₃), carbon monoxide (CO), sulfur oxides (SO_x), nitrogen oxides (NO_x), and lead (Pb). The NAAQS were established to regulate the emissions of the criteria pollutants using human health-

based and/or environmentally based criteria for setting permissible levels. The criteria pollutants are described in more detail below:

Particle Pollution – often referred to as Particulate Matter (PM):

- PM includes the very-fine dust, soot, smoke, and droplets formed from chemical reactions and incomplete burning of fuels.
- The fine particles of PM can get deep into the lungs, causing increased respiratory illnesses and tens of thousands of deaths each year.
- PM is defined as any particle with an equivalent aerodynamic diameter of less than or equal to 10 microns (**PM₁₀**) and is further subdivided to include a separate standard for particles with an equivalent aerodynamic diameter of less than or equal to 2.5 microns (**PM_{2.5}**).

Ground-Level Ozone (O₃):

- O₃ is a primary component of smog that causes human health problems and damage to forests and agricultural crops.
- Repeated exposure to O₃ can make people more susceptible to respiratory infections and lung inflammation.
- Though there is a NAAQS, **O₃ is not emitted directly into the air.**
- Two types of compounds that are the main ingredients (precursors) in forming ground-level O₃ in the presence of ultraviolet (UV) light include:
 - **Volatile Organic Compounds (VOCs):** Defined as “any compound of carbon, excluding carbon monoxide (CO), carbon dioxide (CO₂), carbonic acid, metallic carbides or carbonates, and ammonium carbonate, which participates in atmospheric photochemical reactions” (40 CFR 51.100). Note that 40 CFR 51.100 also exempts compounds based on their negligible photochemical reactivity. Examples of these exempt compounds include methane, ethane, acetone, et al. Common sources of VOCs include gas and diesel-fueled automobiles, fuel storage containers, and solvents used in paints and degreasers.
 - **Nitrogen oxides (NO_x):** Provides the reddish-brown tint in smog. These are produced from the burning of fossil fuels (e.g., gasoline, coal, or oil).

Carbon Monoxide (CO):

- CO is produced when fossil fuel burns incompletely because of insufficient oxygen (O₂).
- Wood, coal, and charcoal fires and gasoline engines always produce CO.
- In the United States, particularly in urban areas, most CO air emissions are from mobile sources.

- CO can cause harmful health effects by reducing O₂ delivery to the body's organs (like the heart and brain) and tissues.

Sulfur Oxides (SO_x):

- Sulfur Oxides are a group of molecules made of sulfur and oxygen atoms, such as Sulfur Dioxide (SO₂), and Sulfur Trioxide (SO₃).
- Since SO₂ is the most common form of the sulfur oxides, the EPA uses it as an indicator for the larger group of SO_x.
- SO₂ in the ambient air is just one of several sulfur oxides that contribute to air quality issues.
- SO_x emissions are produced from fossil fuel combustion at power plants (73 percent) and other industrial facilities (20 percent)
- SO_x is linked to several adverse effects on the respiratory system.

Nitrogen Oxides (NO_x):

- Nitric Oxide (NO), Nitrogen Dioxide (NO₂), and nitrate radicals (NO₃) are collectively called Nitrogen Oxides (NO_x)
- NO₂ is a subgroup of nitrogen oxides and is the most environmentally concerning component. It also acts as an indicator for the presence of the larger group of NO_x.
- NO_x forms quickly from vehicle, power plant, and off-road equipment emissions.
- NO_x contributes to the formation of ground-level O₃ and fine particle pollution.
- NO_x causes airway inflammation and can increase breathing problems for people with compromised respiratory systems (e.g., asthma).

Lead (Pb):

- Pb is a metal found naturally in the environment as well as in manufactured products.
- Prior to 1980, the major sources of Pb were on-road vehicles. As a result, the EPA removed Pb from motor vehicle gasoline, resulting in a 95% decline in Pb emissions between 1980 and 1999.
- Today, the major sources of Pb are ore and metals processing (e.g., lead smelters).
- Depending on the level of exposure, Pb can adversely affect the nervous system, kidney function, immune system, reproductive and developmental systems, and the cardiovascular system.

1.5.2 Hazardous Air Pollutants (HAPs)

According to the EPA (USEPA 2016), “Hazardous air pollutants, also known as toxic air pollutants or air toxics, are those pollutants that are known or suspected to cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental effects.” HAPs include the toxic compounds regulated under Section 112(b) of the CAA. The EPA has been charged with continually analyzing available data on HAPs and revising the regulated list of HAPs. The EPA has also established procedures for both “listing” and “delisting” HAPs. A total of 189 compounds were on the original HAP list, though four compounds have since been removed from this list. These compounds include hydrogen sulfide, in December 1991, caprolactam in June 1996 (61FR30816), ethylene glycol monobutyl ether (EGBE) in November 2004 (69FR69320), and methyl ethyl ketone (MEK) in December 2005 (70FR75047). Changes to the HAPs list are found in 40 CFR Part 63, Subpart C. Since the information contained within this document is for NEPA and General Conformity, the inclusion of HAP emissions is purely informational.

1.5.3 Greenhouse Gases (GHGs)

The emissions of GHGs have garnered more attention in recent years as their potential impact on global climate change has been explored in greater detail. Consequently, the world population’s contribution to GHG emission has been under increased scrutiny. Some GHGs, such as carbon dioxide (CO₂), occur naturally and are emitted into the atmosphere through natural processes as well as human activities. Other GHGs (e.g., fluorinated gases) are created and emitted solely through human activities. The principal GHGs that enter the atmosphere because of human activities are CO₂, methane (CH₄), nitrous oxide (N₂O), and fluorinated gases.

- CO₂ enters the atmosphere through the burning of fossil fuels, (which include oil, natural gas, and coal), solid waste, trees and wood products, and through other chemical reactions (e.g., cement manufacturing). CO₂ is removed (or sequestered) from the atmosphere when it is absorbed by plants and the ocean as part of the global carbon cycle.
- CH₄ is emitted during the production and transport of coal, natural gas, and oil. CH₄ emissions also result from livestock and other agricultural practices and by the decay of organic waste in municipal solid waste landfills.
- N₂O is emitted during agricultural and industrial activities, as well as during combustion of fossil fuels and solid waste.
- Hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride are powerful, synthetic GHGs that are emitted from a variety of industrial processes. Fluorinated gases are sometimes used as substitutes for ozone-depleting chemicals (i.e., CFCs, HCFCs, and halons).

GHGs are assigned a Global Warming Potential (GWP), a measurement of how much heat the gas traps in the atmosphere calculated over a specific time interval, typically 100 years. The higher the GWP, the greater the potential for the gas to trap heat, and the more harmful the gas is regarded. CO₂ is used as the baseline gas and is assigned a GWP of 1. GHG emissions are converted into equivalent CO₂ (CO₂e) by taking the product of the emissions of each GHG and its respective GWP. Table A-1 of 40 CFR 98 provides the GWPs for several GHGs and is shown in Table 1-1. The GWP values used to calculate GHG emissions throughout this document are subject to change due to new data becoming available but are considered current as of May 2021. The total GHG emissions are calculated by summing all emissions from each gas and are generally derived using the following equation:

$$E(CO_2e) = \sum_{i=1}^n [E(GHG)_i \times GWP(GHG)_i]$$

Equation 1-2

Where,

E(CO₂e)	=	Greenhouse gas emissions expressed as CO ₂ equivalent (CO ₂ e)
E(GHG)_i	=	Emissions of individual GHG species i
GWP(GHG)_i	=	Global warming potential for GHG species i
i	=	GHG species, most commonly CO ₂ , CH ₄ , and N ₂ O

Table 1-1. Global Warming Potentials

1.6 Document Organization

This document is organized into chapters which are specifically related to facilities or processes typically found at Air Force installations. Chapter topics may or may not correspond directly to source types identified in EPA, state, or local guidance documents, but the intent is to consider sources usually associated with a process. This document specifically addresses mobile sources of air emissions. Guidance for addressing stationary or transitory sources of air pollutants may be found in the *Air Emissions Guide for Air Force Stationary Sources* or *Air Emissions Guide for Air Force Transitory Sources*.

2.0 AIRCRAFT FLIGHT OPERATIONS (AOPS)

2.1 Introduction

Generally speaking, there are two types of aircraft: fixed-wing or rotary. A fixed-wing aircraft, also known as planes, are heavier-than-air flying machines that are capable of flight by using wings to generate lift via the aircraft's forward airspeed and the shape of the wings. Rotary aircraft, also known as helicopters, are heavier-than-air flying machines that use rotary wings or blades to generate lift. These wings or blades are mounted on a mast, known as a rotor, which they revolve around. Rotorcraft generally include aircraft where one or more motors provide lift throughout the entire flight.

Emissions from stationed aircraft and transient aircraft operations typically account for the bulk of the mobile source emissions associated with an Air Force Base. Emissions from aircraft flight operations include emissions from aircraft training and mission flight operations, engine testing, and emissions from each aircraft's associated Auxiliary Power Units (APUs). Aircraft flight operations result in the release of criteria pollutants, GHGs, and HAPs to the atmosphere.

Aircraft engine emissions can be classified as either stationary or mobile in nature depending upon whether the engine is physically attached to the aircraft (mobile) or removed from the aircraft and secured to a stationary device such as a test stand (stationary). Emissions from DAF aircraft training and mission flight operations, as well as trim pad and on-wing engine testing, are considered mobile in nature because the engine is secured to the aircraft (which is considered a mobile source). Operations in which the engine is removed from the aircraft and secured to a non-mobile device (i.e., in engine test cells or on outdoor test pads) result in emissions that are considered stationary. Calculations of these stationary emissions are described in the *Air Emissions Guide for Air Force Stationary Sources*.

Additionally, some aircraft are outfitted with small turbine engines known as APUs that provide auxiliary power to the aircraft while on the ground, and occasionally through takeoff and climb out modes. APUs are sources of air pollution and, similarly to aircraft engines, are regarded as mobile sources unless operating after being removed from the aircraft and secured to a stationary stand.

Finally, it is important to note that the modelling input parameters (e.g., power settings, EFs, and fuel flow rates) are derived from engine testing on the ground and intended for aircraft engine test cells (a stationary source that is regulated) and are indirectly applied to in-flight and ground operations. Therefore, be aware of the relatively poor resulting data quality of any estimate of any aircraft flight operation.

2.2 Mixing Zone Height and Region of Influence

2.2.1 Mixing Height

Under the EPA procedures, an emissions inventory for aircraft operations focuses only on pollutants emitted in the vertical column of air (generally bound by the perimeter of the base) referred to as the “mixing zone.” The mixing zone is the lower layer of atmosphere where air pollutant mixing occurs (and, therefore, chemical reactions occur) and above which there is a negligible effect on ground-level air pollutant concentrations. This mixing zone portion of the atmosphere begins at the earth's surface and ranges from several hundred to several thousand feet in altitude. The default mixing zone height (mixing height) defined by the EPA is 3,000 feet (ft) Above Ground Level (AGL) [see 40 CFR 93.153 (c) (2) (xxii)] which shall be used for air quality models. However, for proposed actions in nonattainment/maintenance areas where the default mixing height results in total net emissions above the de minimis thresholds, a lower location-specific mixing height can be used if the location-specific mixing height will result in de minimis emissions (i.e., the location-specific mixing height must be less than the 3,000 ft AGL default). Generally, the default mixing zone height of 3,000 feet AGL should be used unless a specific height is prescribed in an applicable State Implementation Plan (SIP).

2.2.1.1 Air Impact Assessments Mixing Height for Criteria Pollutants

For air impact assessments under NEPA and General Conformity, a locally calculated mixing height may be used to demonstrate insignificant (de minimis) air quality impacts associated with a proposed action. In accordance with General Conformity, 40 CFR 93.153(c)(2)(xxii), a “Federal agency can use 3,000 feet above ground level as a default mixing height, unless the agency demonstrates that use of a different mixing height is appropriate because the change in emissions at and above that height caused by the Federal action is de minimis.” Additionally, in accordance with the 40 CFR 93 Preamble, EPA “added regulatory language to sub-paragraph (xxii) to allow federal agencies to use a different mixing height if they can demonstrate that emissions at and above that height are de minimis.” Therefore, a calculated local mixing height would only be used for air impact assessments (NEPA and General Conformity assessments) and only if it would result in a de minimis level of emissions. In other words, the default 3,000 feet mixing height will always be used initially and, if an action’s emissions are not de minimis, the calculated local average mixing height may be used if (and only if) the adjustment in emission would result in the action being de minimis. Therefore, the local average mixing height should never be used in areas where the average calculated local average mixing height is greater than 3,000 ft.

The *DAF Air Quality Environmental Impact Analysis Processes (EIAP) Guide* should be consulted for more details on the specific use of local average mixing height. Additionally, to ensure proper use and to refine emissions estimates, contact the AFCEC Air Quality Subject

Matter Expert to obtain approval and location-specific data for seasonal or annual average mixing heights.

2.2.1.2 Air Impact Assessments Mixing Height for Greenhouse Gasses (GHGs)

Unlike criteria pollutants, the impact of GHGs is at a global-scale and therefore the impact of GHGs at the microscale (local area) is scientifically incalculable. Both the current EPA method for estimating aircraft flight operations emissions (EPA 420-R-92-009) and the General Conformity Rule (40 CFR 93 Subpart B) call for only including criteria pollutant emissions below the mixing height. Given, the mixing height is only associated with microscale air quality criteria pollutant modeling, use of the mixing height for GHG emissions modeling could be considered inadequate. Therefore, logically, if flight-specific fuel consumption data can be reasonably foreseeably predicted, aircraft flight operations GHG emissions used for the “relative comparison analysis” should be calculated using the flight-specific fuel consumption data.

As a result, the Air Force methodology for estimating criteria pollutants, emissions below the mixing height, should NOT be used as a standardized methodology for performing a relative comparison analysis for GHGs. GHG emissions should be estimated for the full extent of aircraft movements as part of the projected net change in GHG emissions and with no altitude restriction (not constrained by the mixing height). Therefore, flight-specific fuel consumption data will be derived from site-specific representative GHG TIMs or TIPs must be used for all impact assessments or emission inventories (default TIMs may only be used for planning purposes).

Note: Due to the complexity and highly technical nature of the methodology of deriving TIMs/TIPs and the need for standardization across the Air Force, only AFCEC/CZTQ may derive site-specific representative GHG TIMs or TIPs.

2.2.2 Region of Influence (ROI)

For air quality impacts assessments, a Region of Influence (ROI) for an action is a three-dimensional vertical column of air within the mixing zone (i.e., up to the mixing height) where pollutant emissions associated with a proposed action will occur. There may be more than one ROI due to the physical and spatial distribution of the emissions sources associated with the proposed action. Each non-contiguous area, nonattainment area, and maintenance area must be considered as a separate ROI. Each ROI requires a separate air quality EIAP assessment which must have a conclusion of air quality impacts for the ROI.

Note: Due to the complex nature, ROI determination must be established by AFCEC/CZTQ for all assessments involving flight operations within any nonattainment or maintenance area.

Figure 2-1. ROI

Additionally, for ROIs within areas that are classified as nonattainment or maintenance for any National Ambient Air Quality Standard (NAAQS), a separate General Conformity assessment for each nonattainment or maintenance area must be performed in tandem with the ROI's overall air quality EIAP assessment (this is generally automated in the Air Conformity Applicability Model [ACAM] if the nonattainment and maintenance areas are selected).

Figure 2-2. Multiple ROIs

All emissions from new aircraft operations associated with a proposed action within the mixing zone must be included in a ROI's air quality EIAP assessment. The mixing zone is the lower layer of atmosphere where air pollutant chemical reactions occur and above which there is a

negligible effect on ground-level air pollutant concentrations. This mixing zone portion of the atmosphere begins at the earth's surface and ranges from several hundred to several thousand feet in altitude. The default mixing zone height (mixing height) defined by the EPA is 3,000 feet (ft) Above Ground Level (AGL) [see 40 CFR 93.153 (c) (2) (xxii)] which shall be used for air quality models. However, for proposed actions in nonattainment/maintenance areas where the default mixing height results in total net emissions above the de minimis thresholds, a lower location-specific mixing height can be used if the location-specific mixing height will result in de minimis emissions (i.e., the location-specific mixing height must be less than the 3,000 ft AGL default). Therefore, initially only air emissions produced below the default 3,000 ft AGL mixing height are considered when assessing ROIs heights and air quality impacts. There are three aircraft operations that will potentially occur below the mixing height: Landing and Takeoff cycles, Closed Pattern cycles (Touch and Goes) and Low Flight Patterns. For estimating the total emissions associated with each type of aircraft operation, a reasonably foreseeable typical flight pattern [in terms of Time-in-Mode (TIM) for fixed-wing or Time-in-Phase (TIP) for rotary] for a specific aircraft operation is multiplied by the reasonably foreseeable worst-case number of the specific aircraft operation per year. Additionally, any reasonably foreseeable Trim Tests and Engine Test Cell activities associated with the proposed action (preferred action and alternatives) must be included in the air quality EIAP assessment.

2.3 Aircraft Flight Operations

Fixed-wing aircraft and rotary aircraft are both heavier-than-air flying machines that are capable of flight by using mechanical powered engines. A fixed-wing aircraft (planes) fly using wings to generate lift via forward airspeed; while a rotary aircraft (helicopters) fly using rotary wings or blades to generate lift. Fixed-wing aircraft require runways to take off, while rotary-wing aircraft can take off from any level surface. Therefore, aircraft flight operations for both are quite different.

Flight operations for aircraft are broken down into “flight cycles” for estimating air emissions. A “flight cycle” is one complete repetitive sequence of flight operations which consists of various “flight modes” (and their corresponding engine “power settings”) for fixed-wing aircraft or “flight phases” (idle, taxi, takeoff, flight, and landing phases) for rotary aircraft.

There are three basic flight cycles:

- **Landing and Takeoff (LTO) Cycle:** A flight operation consisting of one complete repetitive takeoff and landing cycle.
- **Closed Pattern (CP) Cycle:** A flight operation consisting of one complete repetitive flight maneuver that involves practice landing on a runway by briefly touching the landing gear to the runway, or coming very close, and transitioning immediately into climb out and associated flying to maneuver into another practice landing.
- **Low Flight Pattern (LFP) Cycle:** A flight operation consisting of one complete repetitive flight cycle below the mixing height that does not include any part of a LTO or CP cycle.

2.3.1 Fixed-Wing Aircraft Flight Operations

2.3.1.1 Fixed-Wing LTO Cycle

The EPA has established formal procedures for calculating exhaust emissions associated with fixed-wing aircraft operations based on a Landing and Takeoff (LTO) cycle (USEPA 1992). Under the EPA procedures, an emissions inventory for aircraft operations focuses only on pollutants emitted in the vertical column of air (generally bound by the perimeter of the base) referred to as the “mixing zone.” Exhaust emissions occurring within this area are calculated for one complete LTO cycle for each aircraft type by applying aircraft engine-specific emission factors.

A sortie may include any number of aircraft flight patterns but only one takeoff and only one return landing. Given this, the number of sorties equates to the number of LTO cycles. Since a LTO cycle is only a fraction of the total flight patterns which make up a sortie (that only includes

the very short beginning and very short ending), a LTO cycle corresponds to two aircraft operations – one arrival and one departure. Therefore, one LTO cycle represents a pair of arrival and departure operations.

Each LTO cycle for fixed-wing aircraft is comprised of four flight modes: taxi/idle, takeoff, climb out, and approach. Each of these modes has a corresponding engine power setting/mode. Engine power modes are aircraft engine operational settings defined by the percent of total engine thrust. The engine power modes for a specific engine are defined by the percent of total thrust the engine was tested at as required by 40 CFR 87, *Control of Air Pollution from Aircraft and Aircraft Engines*. Engine power modes are considered interchangeable with aircraft flight modes because during each aircraft flight mode of operation, the aircraft engines operate at a standard power setting for a given aircraft category. The four flight modes and corresponding engine power settings are:

- **Idle (Taxi) Mode:** The engine idle portion of an LTO Cycle which includes all on-ground idle portions of a flight cycle which includes both the engine startup/warmup time before taxiing for departure and the engine cooldown/shutdown time period. The Taxi Mode portion of an LTO Cycle also includes the total time the plane spends taxiing. Taxi time includes taxiing times from the parking area to the takeoff/landing area (Taxi Out) and, upon landing, taxiing from the takeoff/landing area to the parking area (Taxi In). The Idle flight mode is performed in the “Idle” engine power setting.
- **Takeoff Mode:** Characterized by full engine thrust, the time it takes the aircraft to reach 500 feet Above Ground Level (AGL). Equates to both the “Military” and/or “Afterburner” engine power setting, dependent on engine capability and local flight requirement.
- **Climb Out Mode:** Starts with the initial aircraft ascent from 500 ft AGL through the aircraft exiting the mixing zone (default is 3,000 ft). The Climb Out flight mode is performed in the “Climb Out” (also known as “Intermediate”) engine power settings.
- **Approach Mode:** Commences with the aircraft return and descent, starting when the aircraft enters the mixing zone to 0 ft AGL (touchdown). The Approach flight mode is performed in the “Approach” engine power setting.

Figure 2-3. Fixed-Wing LTO Cycle

2.3.1.2 Fixed-Wing CP Cycle

A Fixed-Wing CP cycle, also known as a Touch and Go (TGO), is a flight maneuver that involves practice landing on a runway by briefly touching the landing gear to the runway, or coming very close, and transitioning immediately into climb out and associated flying to maneuver into another practice landing (See Table 2-9). A CP cycle is effectively a combination of one LTO cycle (specific to the CP cycle) and one LFP for the portion of the return flight below the mixing height.

Figure 2-4. Fixed-Wing CP Cycle

2.3.1.3 Fixed-Wing LFP Cycle

A Fixed-Wing LFP cycle is a flight maneuver that occurs below the mixing height (EPA default = 3,000 ft AGL) that is not part of an LTO or CP cycle. Generally, LFPs are flown only in the "Intermediate" and/or "Approach" engine power modes. If the aircraft is level or ascending the aircraft is generally flying in the "Intermediate" engine power setting and if the aircraft is descending the aircraft is generally flying in the "Approach" engine power setting.

Figure 2-5. Fixed-Wing LFP Cycle

2.3.2 Rotary (Helicopter) Aircraft Flight Operations

Fixed-wing aircraft and rotary aircraft are both heavier-than-air flying machines that are capable of flight by using mechanical powered engines; however, the difference in means of flight also dictates different flight operations. A fixed-wing aircraft generally uses runways to take off and land, while rotary-wing aircraft can take off from any level surface and flies at much lower altitudes. Therefore, rotary aircraft flight patterns are described in terms of “flying phases” rather than “flight modes” (as with fixed-wing aircraft). As with flight modes, flying phases correspond to specific engine power thrust settings:

- **Idle Phase:** Is the flying phase portion of an LTO Cycle which includes all on-ground idle portions of a flight cycle. The Idle Phase is performed in the “Idle” engine power setting.
- **Taxi Phase:** Is the flying phase portion of an LTO Cycle which includes the total time the helicopter spends taxiing. The Taxi Phase is performed in the “Taxi” engine power setting.
- **Takeoff Phase:** Is the flying phase portion of an LTO Cycle which includes the vertical and horizontal ascent from a specified takeoff point. The Takeoff Phase is performed in the “Takeoff” engine power setting.
- **Landing Phase:** Is the flying phase portion of an LTO Cycle which includes the vertical and horizontal descent to a specified landing point. The Landing Phase is performed in the “Landing” engine power setting.
- **Flight Phase:** Is the flying phase portion of a LFP or CP, which includes the portions of flying between 1,000 ft AGL and the mixing height. The Flight Phase excludes all portions of an LTO Cycle. The Flight Phase is performed in the “Flight” engine power setting.

2.3.2.1 Rotary LTO Cycle

Because rotary aircraft fly at lower altitudes, the LTO cycle only accounts for takeoff and landings below 1,000 ft AGL. Therefore, rotary aircraft do not follow a Fixed-Wing LTO Cycle and have an independent LTO Cycle (a Rotary LTO Cycle, which reflects only flight below 1,000 ft AGL).

A Rotary LTO Cycle is one complete takeoff and landing cycle, consisting of the time duration in four of the five flying phases (i.e., Time In Phase or TIP). “Time In Phase” or “TIP” is the time spent, during a representative flight cycle, in each of the flying phases: idle, taxi, takeoff, and landing phases:

- **Idle Phase:** Is the flying phase portion of an LTO Cycle which includes all on-ground idle portions of a flight cycle which includes both the engine startup/warmup time before taxiing for departure and the engine cooldown/shutdown time period.
- **Taxi Phase:** Is the flying phase portion of an LTO Cycle which includes the total time the helicopter spends taxiing. Taxi time includes taxiing times from the parking area to the takeoff area and, upon landing, taxiing from the landing area to the parking area.
- **Takeoff Phase:** Is the flying phase portion of an LTO Cycle which includes the vertical and horizontal ascent from a specified takeoff point. It is assumed the takeoff phase starts on the ground and ends at 1,000 ft AGL.
- **Landing Phase:** Is the flying phase portion of an LTO Cycle which includes the vertical and horizontal descent to a specified landing point. It is assumed the landing phase starts at 1,000 ft AGL and time is in general equal to the takeoff TIP. Therefore, TIP for landing ($TIP_{Landing}$) is equal to the TIP for takeoff ($TIP_{Takeoff}$).

Figure 2-6. Rotary LTO Cycle

A Rotary LTO does not include any flight time above the 1,000 feet AGL. A “representative Rotary LTO Cycle” is a single departure and arrival cycle that is statistically characteristic of all Rotary LTO cycles flown in an average calendar year. A representative Rotary LTO Cycle is derived through frequency weighted averaging all significant departure and arrival cycles within an average calendar year.

2.3.2.2 Rotary CP Cycle

A Rotary CP cycle (also known as a Touch and Go [TGO] cycle) is a flight maneuver that involves practice landing on a runway by briefly touching the landing gear to the runway, or coming very close, and transitioning immediately into climb out and associated flying to maneuver into another practice landing (See Figure 2-7. Rotary CP Cycle). A CP cycle is simply a combination of one LTO cycle (specific to the CP cycle) and one LFP for the portion of the return flight below the mixing height.

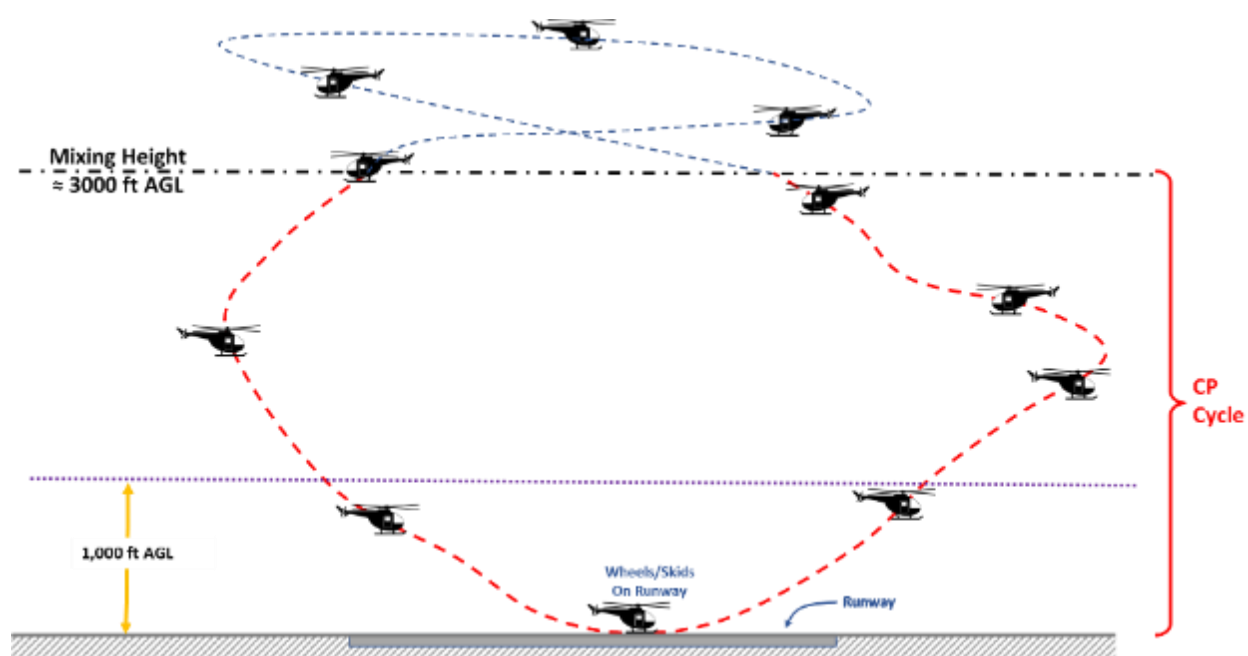

Figure 2-7. Rotary CP Cycle

2.3.2.3 Rotary LFP Cycle

A LFP flying cycle only occurs below the mixing height (EPA default = 3,000 ft AGL) and does not include any part of an LTO or CP cycles. Generally, LFPs are flown only in the flight “Flying Phase” engine power mode. Rotary LFP are often attributed to trips to and from mission destinations.

Figure 2-8. Rotary LFP Cycle

2.4 Jet Fuel

Both military aircraft engines (either fixed-wing or rotary) and APUs consume JP-8 fuel, while their commercial counterparts consume a nearly identical fuel known as Jet-A. While most aircraft operations involve engines that use either JP-8 or Jet-A fuel, small, piston engine-driven aircraft that consume aviation grade gasoline, or AVGAS, may periodically operate on a DAF installation. Additionally, recent Air Force and commercial initiatives are expected to result in the increased use of so-called synthetic aviation fuel or “synfuel” over the next several years. These “synfuels” are derived from either coal or natural gas using the Fischer-Tropsch (FT) process and burn much cleaner than fuels produced from crude oil. Regardless of fuel type, emissions of concern from aircraft operations and engine testing include the criteria pollutants (VOC, CO, NO₂, PM_{2.5}, PM₁₀, and SO₂), and HAPs (including, but not limited to benzene, naphthalene, and 1,3-butadiene) that are commonly associated with fuel combustion processes.

2.4.1 Synthetic Aviation Fuel

Currently, there are on-going Department of Defense (DoD) and DAF initiatives to reduce dependency on foreign petroleum sources. This includes development of battlefield fuels with essentially no sulfur and reduced aromatic content using FT gasification technology on domestic energy sources such as coal and natural gas. These “synthetic” fuels will increasingly be used to offset conventional JP-8 and diesel fuels in Air Force equipment, particularly aircraft. Testing and certification of 50-50 blends of petroleum- and FT-based JP-8 in B-52s has already been completed by the Air Force Research Laboratory (AFRL). The data indicates that the 50-50 blend reduces SO₂, CO₂, and PM emissions considerably (DAF 2007). When estimating emissions from aircraft operations in which a synthetic fuel blended with petroleum JP-8 was used, the following emission reduction factors should be applied:

Table 2-1. Fuel Emission Reduction Factors (FERFs) for JP-8/Synthetic Fuel Blends

Pollutant	Reduction Factor (%)
PM	35
SO ₂	50
CO ₂	1.8

SOURCE: DAF Alternative Fuels Program, AFRL/WS//06-0078. 22nd Annual UC Symposium on Aviation Noise and Air Quality. March 2007.

2.5 Emission Factors

Air pollutant EFs for aircraft operations include emissions from aircraft engines (either fixed-wing or rotary) and APUs used on the airframe. The EFs have been developed through testing by either the manufacturers themselves or another party. Though the EFs were developed for stationary jet engine testing and are most suited for this application, it is considered acceptable to use them for estimating emissions from aircraft flight operations. Criteria pollutant and GHG EFs for each engine are provided in Table 2-9 while speciated VOC and HAP EFs for select engines and APUs are provided in Table 2-10. Criteria pollutants for some APUs are provided in Table 2-12. The aircraft engine EFs presented in Table 2-9 are provided for each power setting which correspond to the flight operating cycle in an LTO cycle. Note that, in several instances, a surrogate engine may have been used to fill data gaps.

2.6 Emissions Calculations

Emissions calculation procedures for aircraft operations under various operational cycles are described in the following paragraphs. EFs and power settings for specific aircraft engines are provided in Table 2-9. For engine models not listed in Table 2-9, contact the Air Quality SME for assistance in selecting a representative surrogate engine.

2.6.1 Fixed-Wing Aircraft Emissions

The EFs listed have been determined through testing and may be found in a variety of sources. It is important to note that some sources, such as the Airport Air Quality Manual and International Civil Aviation Organization (ICAO), do not provide PM₁₀ and PM_{2.5} EFs directly (ICAO 2011). For those sources, the total PM was calculated and was conservatively assumed to be equal to PM₁₀. A similarly conservative estimate was made for PM_{2.5} by assuming that 90% of the total PM₁₀ value is composed of PM_{2.5}. These assumptions are noted in the appropriate tables. Additionally, there are several engines for which some EF data may have been missing. For these engines, either the EFs from a surrogate were used or the missing data was interpolated or

extrapolated. These values are clearly marked in the tables with an (S) for EFs in which a surrogate was used, or a (C) when the values were calculated. The engines used as surrogates are provided in the notes. Common airframe/engine combinations for military fixed-wing, rotary, and commercial aircraft are provided in Table 2-6, Table 2-7, and Table 2-8.

2.6.1.1 LTO Emissions

LTO emissions are calculated based on the type of aircraft, the engine model and number per airframe, the operational mode and TIM for each mode, and the power setting associated with each operational mode. The fuel flow rate associated with each power setting, engine specific EFs, the mixing zone height, and the number of LTO cycles conducted during the year are also considered in the LTO emissions calculation. As TIM and fuel flow rate for each power setting vary among aircraft engines and airframes, the calculation procedure will need to be repeated for individual aircraft types. A description of the operating modes for commercial and military aircraft and the default TIMs are provided in Table 2-4 and Table 2-5 respectively.

Aircraft engine emissions per airframe based on an LTO cycle account only for those emissions occurring below the mixing height and are calculated as follows:

$$E(\text{Pol})_{\text{Aircraft}} = \sum_{i=1}^n \left[\frac{\text{TIM}_i}{60} \times \frac{\text{FFR}_i}{1,000} \times \text{EF}(\text{Pol})_i \times \frac{\text{FERF}(\text{Pol})}{100} \right] \times N \times C \quad \text{Equation 2-1}$$

Where,

E(Pol)_{Aircraft}	=	Annual pollutant emissions per engine on airframe being evaluated (lb/yr)
N	=	Number of units (engines) per airframe being evaluated
60	=	Factor to convert minutes to hours
1000	=	Factor to convert lb fuel burned to 10 ³ lb fuel burned (lb/10 ³ lb)
i	=	Mode identifier. 1 = Idle in/out, 2 = Takeoff, 3 = Afterburner Takeoff, 4 = Climb out, and 5 = Approach
TIM_i	=	Time spent in each mode, referred as “Power Setting” in Table 2-9 and Table 2-10, in per LTO cycle (min/cycle)
FFR_i	=	Fuel flow rate during operational mode per aircraft engine (lb/hr)
EF(Pol)_i	=	Pollutant emission factor for specified mode (lb/10 ³ lb fuel burned)
FERF(Pol)	=	Fuel emission reduction factor, if applicable (%). In cases where alternative fuel is not used, then a value of 100% must be used.
100	=	Factor to convert percent to a fraction (%)
C	=	Number of annual LTO Cycles (cycle/yr)

Default TIMs may only be used for planning purposes. Site-specific TIMs must be used for all impact assessments and emissions inventories. Due to the complexity and highly technical nature of the methodology of deriving site-specific TIMs and the need for standardization across the Air Force, only AFCEC/CZTQ may derive site-specific TIMs.

Note that when calculating the emissions for each LTO, the pollutant EF for the appropriate power setting must be selected from Table 2-9. For engines equipped with afterburner, 50% of the total time in “takeoff” is assumed to be in the “military” power setting and 50% in the “afterburner” power setting. Also, some aircraft may utilize a different power setting during a flight mode than what is given in Table 2-4 (e.g., an engine may be in the “military” power setting during the “climb out” phase of the LTO). Typically, however, the engine power settings correspond to the flight modes and should be selected when calculating emissions for an LTO.

Some of the data required to calculate aircraft emissions per LTO cycle may be found in the following tables:

- FERF, if synthetic fuel blends are used, are provided in Table 2-1
- Regional sulfur content of JP-8, if required for enhanced accuracy, is provided in Table 2-2
- TIM spent in each LTO cycle mode is found in Table 2-5
- Power settings and fuel flow rates for each LTO cycle mode and associated engine specific EFs are found in Table 2-9 and Table 2-10

2.6.1.2 CP Emissions

Used primarily for NEPA/General Conformity air impact studies under EIAP assessments, Touch and Go (TGO) and Low Fly By (LFB) training operations may dictate the need to conduct aircraft operations that deviate from a standard LTO cycle. A TGO cycle is a common flight maneuver that involves practice landing on a runway by briefly touching (or simulating the touching of) the landing gear to the runway and transitioning immediately into climb out. During a LFB, the aircraft generally drops below the mixing height and returns to a higher altitude without touching (or simulating the touching of) the landing gear to the runway. TGO and LFB emissions are calculated in essentially the same manner as LTO emissions; however, only some modes of a complete LTO are considered. For TGO emissions estimating, generally only the default TIMs for approach, takeoff, and climb out are used. For LFB emissions estimating, one half of the default TIMs for approach and climb out are used.

2.6.1.3 LFP Emissions

Another training operation primarily used for NEPA/General Conformity air impact studies under EIAP is a Low Flight Pattern (LFP), which is any aircraft maneuver below the mixing zone height and not associated with an LTO, TGO, or LFB. When calculating emissions in this manner, one must know both the number of LFPs per year and the average time of the LFP. Generally, for LFP emissions estimating, use only the intermediate power setting for the entire time of the LFP.

2.6.2 Auxiliary Power Unit Emissions

APU emissions are based on the APU model associated with each aircraft type, EFs, and the length of time the APU was operating during an LTO cycle. The EFs for APUs are presented in units of lb/hr, so the operating time for each APU must be known or approximated. Common aircraft/APU combinations and typical APU operating times are found in Table 2-6, Table 2-7, and Table 2-8. Criteria pollutant and GHG EFs for APUs can be found in Table 2-12.

APU emissions are calculated using a two-step approach that consists of the following:

- 1) Calculate pollutant emissions for each APU per LTO; and
- 2) Multiply the emissions per LTO by the total number of LTO cycles per year.

These steps are simplified by the following equation:

$$E(Pol)_{APU} = L \times N \times \frac{OT}{60} \times EF(Pol) \times \frac{FERF(Pol)}{100}$$

Equation 2-2

Where,

E(Pol)_{APU}	=	Annual pollutant emissions produced by the APU for the aircraft being evaluated (lb/yr)
L	=	Number of LTO cycles per year (cycle/yr)
N	=	Number of units (APUs) per airframe being evaluated
OT	=	Operating time per LTO cycle (min/cycle)
60	=	Factor to convert minutes to hours (min/hr)
EF(Pol)	=	APU-specific emission factor for each pollutant (lb/hr)
FERF(Pol)	=	Fuel emission reduction factor, if applicable (%). In cases where alternative fuel is not used, then a value of 100% must be used.
100	=	Factor to convert percent to a fraction (%)

Some of the data required to calculate emissions from APU operations may be found in the following tables:

- Typical airframe/APU combinations and operating times are provided for military fixed-wing, rotary, and commercial aircraft in Table 2-6, Table 2-7, and Table 2-8, respectively.
- Criteria and GHG EFs are provided in Table 2-12
- Speciated VOC and HAP EFs for select APUs are provided in Table 2-10

2.6.3 Trim Pad and On-Wing Testing

Emissions associated with trim pad and on-wing testing are based on the type of aircraft, engine model, testing times, the power settings and associated fuel flow rates, and engine-specific EFs. Estimating emissions from aircraft engine testing may be challenging since the data required for calculations may be difficult to obtain. Emissions are calculated by multiplying the fuel flow rate at the selected power setting by the amount of time the engine is operated at that power setting and applying pollutant specific EFs. After the emissions are calculated for a pollutant at each power setting, the values are summed to obtain the total annual emissions of that pollutant. Aircraft engine emissions from trim pad and on-wing testing may be calculated using a three-step approach that consists of the following:

- 1) Determine the engine operating mode based on the aircraft fuel flow rate at each test setting.
- 2) Calculating pollutant emissions using the appropriate EF and total time spent within each operating mode.
- 3) Summing emissions from each mode to obtain annual emissions for that engine.

These steps are simplified by the following equation:

$$E(Pol)_{Testing} = \sum_{i=1}^n \left[\frac{TIM_i}{60} \times \frac{FFR_i}{1000} \times EF(Pol)_i \times \frac{FERF(Pol)}{100} \right]$$

Equation 2-3

Where,

E(Pol)_{Testing}	= Annual pollutant emissions produced by the engine being evaluated (lb/yr)
60	= Factor to convert minutes to hours
1000	= Factor to convert lb fuel burned to 10 ³ lb fuel burned (lb/10 ³ lb)
i	= Mode identifier. 1 = Idle in/out, 2 = Takeoff, 3 = Afterburner Takeoff, 4 = Climb out, and 5 = Approach.
TIM_i	= Time spent in the fuel flow rate range specified for the entire year (min/yr)
FFR_i	= Fuel flow rate during operational mode (lb/hr)
EF(Pol)_i	= Pollutant emission factor for specified mode (lb/10 ³ lb fuel burned)
FERF(Pol)	= Fuel emission reduction factor, if applicable (%). In cases where alternative fuel is not used, then a value of 100% must be used.
100	= Factor to convert percent to a fraction (%)

Note that the TIM_i refers to the total time spent within the fuel flow rate range corresponding to an operating mode, and not the aircraft default TIMs as these apply to aircraft flight patterns.

The fuel flow rate and engine specific EFs required to calculate emissions using Equation 2-3 may be found in Table 2-9 and Table 2-10. The appropriate EF is determined by the engine's fuel flow rate and, ideally, the fuel flow rates and operating times for each test profile are recorded by a data logger. Since the fuel flow rate will vary from each test and operating mode, the EFs developed for each mode on each aircraft engine are deemed suitable across a range of fuel flow rates. This means that while the following tables provide an EF for a specific engine at a precise fuel flow rate, that EF is valid for a range of fuel flow rates and should be used for emissions calculations. The tables in this guide only provide the specific fuel flow rates and corresponding EF at which the engine was tested. To find the range of fuel flow rates and appropriate EF, refer to the "Aircraft Engine Testing" section of the *Air Emissions Guide for Air Force Stationary Sources* since off-wing engine testing is more common and a stationary source of emissions (and therefore subject to more regulation).

The fuel flow rate ranges provided in the *Air Emissions Guide for Air Force Stationary Sources* for most power settings were determined by taking the midpoint of the fuel flow rates between power settings at which the engine was tested. The exception to this method is for the afterburner (AB) setting since the AB setting uses more fuel and combustion efficiency is drastically different from the other operating modes. For those engines equipped with AB, the engine is assumed to operate at 100% power when in the military setting, so any fuel flow rate greater than that of the military operating mode for which the engine was tested is assumed to be in AB and the appropriate AB EF should be selected. Refer to the tables in the *Air Emissions Guide for Air Force Stationary Sources* for additional information.

2.6.4 Rotary Aircraft Emissions

Rotary aircraft (helicopter) flight operations emissions are estimated based on multiplying the emissions from a single representative flying phase cycle with the average number of annual flight operations. The annual flight operations emissions are calculated in a three-step approach that consists of the following:

1. Calculate pollutant emissions for each flight phase of the representative flight cycle,
2. Sum the emissions for each phase to obtain the flying phase cycle emission values, and
3. Multiply the flying phase cycle emission values by the number of annual Flight Cycles.

These steps are simplified by the following equation:

$$E(Pol) = \sum_{i=1}^n \left[\frac{TIP_i}{60} \times \frac{FFR_i}{1000} \times EF(Pol)_i \right] \times N \times C$$

Equation 2-4

Where,

E(Pol)	=	Annual pollutant emissions from flight operations (ton/yr)
TIP_i	=	Time In Phase or time spent in “i” flight phase, referred as “Power Setting” in Table 2-9 and Table 2-10 (min/cycle)
i	=	Phase identifier (1 = idle, 2 = taxi, 3 = takeoff, 4 = flight, and 5 = landing)
60	=	Factor for converting minutes into hours (min/hr)
FFR_i	=	Fuel flow rate per engine for the flight phase (lb fuel/hr)
1000	=	Factor for converting lb fuel to 1,000 lb fuel
EF(Pol)_i	=	Pollutant-specific emission factor for flight phase (lb/1,000 lb fuel)
N	=	Number of engines the aircraft has
C	=	Number of annual Flight Cycles (cycle/yr)

Site-specific TIPs must always be used. Due to the complexity and highly technical nature of the methodology of deriving site-specific TIPs and the need for standardization across the Air Force, only AFCEC/CZTQ may derive site-specific TIPs.

2.6.5 Calculating SO₂ Emissions

SO₂ emissions are created when sulfur in the fuel reacts and combines with oxygen during the combustion process. Fuels with higher sulfur content will produce higher amounts of SO₂ than low-sulfur fuels. It is generally assumed that during combustion, all sulfur in the fuel reacts to form SO₂ or sulfates. The sulfur content in commercial jet fuel is limited to 0.3 weight percent (wt. %); however, the sulfur content for most in-use fuel is significantly less than this limit. For air impact assessments under NEPA and General Conformity, the use of a national average sulfur content is appropriate for estimating sulfur emissions from aircraft operations. For JP-8 fuel, the weighted national average was calculated using data obtained from the Defense Logistics Agency (DLA), Defense Energy Support Center, *Petroleum Quality Information System Fuels Data* (1997-2013). **Using this national weighted average, a national EF was derived and should be used as the default value for all aircraft engines within the continental United States when estimating SO_x emissions.** For enhanced accuracy, regional averages have also been calculated. The default national average and regional averages are provided in Table 2-2.

The sulfur content in fuel varies significantly by the region in which the fuel is obtained. For a more accurate accounting of SO_x emissions from aircraft flight operations, a base-specific SO_x EF may be estimated using the weight percent sulfur content of the fuel as provided by the fuel supplier. Assuming all the sulfur in the fuel is converted to SO₂ during the combustion process, a base-specific SO_x EF may be calculated according to the following equation:

$$EF(SO_x) = S \times 20$$

Equation 2-5

Where,

EF(SO_x) = SO_x emission factor (lb SO₂/10³ lb fuel burned)

S = Weight percent sulfur content of the fuel

20 = Conversion factor derived by converting the weight percent of sulfur to a weight fraction, converting this into units of lb/1,000 lb, and then multiplying by the ratio of the molecular weight of SO₂ to the molecular weight of sulfur

Table 2-2. Average Sulfur Content of JP-8

Geographic Region	States or Countries	Weighted-Average Sulfur Content (Weight %)	Emission Factor (lb/10³ lb fuel)
National Average		0.054	1.07
1. East Coast U.S.	ME, VT, NH, MA, RI, CT, NY, PA, NJ, DE, MD, VA, WV, NC, SC, GA, FL	0.110	2.19
2. East Central U.S.	ND, SD, MN, IA, NE, WI, MI, OH, KY, TN, IN, IL, MO, KS, OK	0.067	1.35
3. Gulf Coast U.S.	AL, MS, AR, LA, TX, NM	0.053	1.05
4. West Central U.S.	MT, ID, WY, UT, CO	0.028	0.56
5. West Coast U.S.	WA, OR, CA, NV, AZ	0.053	1.07
Middle East	Kuwait, Bahrain, Pakistan, United Arab Emirates	0.069	1.39
European	Europe, Israel, Turkey	0.118	2.37
Pacific	Korea, Japan, HI, AK, Australia, Russia, Singapore	0.096	1.91
Caribbean	Coastal Aruba	0.045	0.89

Source: *Petroleum Quality Information System Fuels Data*. Defense Logistics Agency, Defense Energy Support Center, 1997-2013. Values were calculated using the weight percent sulfur for years 1997 – 2013. Emission factors were calculated using Equation 2-5, though note that the values may not be exactly 20 times the weighted average due to rounding.

2.6.6 Calculating HAP Emissions

Since the information contained within this document is for NEPA and General Conformity, the inclusion of HAP emissions is purely for informational purposes. Despite the limited information available, there are aircraft engine-specific and APU-specific HAP EFs provided in Table 2-10.

2.6.7 Lead (Pb) Emissions

Prolonged exposure to high levels of Pb may result in harmful health effects, especially in young children. Though Pb is a criteria pollutant, this document does not provide any Pb EFs for aircraft and APUs because of the transition to unleaded aviation fuel.

2.6.8 Greenhouse Gas (GHG) Emissions

Since GHG emissions are becoming increasingly more important, it is common to record the carbon dioxide (CO₂), methane (CH₄), and nitrous oxide (N₂O) emissions produced when measuring emissions from mobile and stationary sources. It is also common practice to report GHG emissions in terms of equivalent CO₂ (CO₂e). This document provides a total GHG composite EF consisting of CO₂, CH₄, and N₂O presented in CO₂e for aircraft in Table 2-3 and Table 2-12 for select APUs. For more guidance on the calculation of GHG emissions, refer to the *DAF Guide to the Mandatory Greenhouse Gas Reporting Rule*.

Table 2-3. GHG Emission Factors for Aircraft Engines

Vehicle Type	Fuel Type	Emission Factors (lb/1000lb fuel)			
		Greenhouse Gas Species			
		CH ₄	N ₂ O	CO ₂	CO ₂ e ^b
Aircraft	Jet Fuel ^a	0.1347	0.02628	3203.44	3214.64
	AVGAS	0.1323	0.02572	3053.40	3064.37

Notes for Table 2-3:

Emission Factors calculated and verified 05/2023

- JP-8 emission factors were used as representative Jet Fuel.
- Equivalent CO₂ (CO₂e) emission factors are the total of the product of CO₂, CH₄, and N₂O and their respective Global Warming Potentials (GWP). GWP used are 1 for CO₂, 25 for CH₄, and 298 for N₂O. JP-8 with a density of 6.71 lb/gal was used for unit conversion. AVGAS with a density of 6 lb/gal was used for unit conversion.

2.6.9 HAP Speciation

Though HAP emissions have been speciated for some engines, there is little data available for most aircraft engines likely found at DAF installations. If speciated HAP data for an engine is unavailable, it is recommended that a surrogate engine is used. If there is no suitable surrogate data available, speciated HAP emissions may be estimated using the total VOC emissions and mass fraction of the speciated HAP. The mass fractions for several HAPs are provided in Table 2-11 and those recommended by the EPA as stated in the document *Recommended Best Practice for Quantifying Speciated Organic Gas Emissions from Aircraft Equipped with Turbofan, Turbojet, and Turboprop Engines*. Emissions of a speciated HAP are calculated by first converting the total VOC emissions to Total Organic Gases (TOG) and multiplying this by the mass fraction of the speciated HAP of interest. This calculation is shown in the following equation:

$$E(Pol) = \frac{E(VOC)}{0.99} \times MF(Pol)$$

Equation 2-6

Where,

E(Pol)	=	Emissions of speciated HAP (lb/yr)
E(VOC)	=	Emissions of total VOC (lb/yr)
0.99	=	Factor converting VOC to TOG
MF(Pol)	=	Mass fraction of the HAP of interest as provided in Table 2-11

2.6.10 International Civil Aviation Organization (ICAO) Emission Factors

The ICAO is a United Nations specialized agency that was created in 1944 with the goal of encouraging the safe and orderly development of international civil aviation. The organization develops and maintains safety standards, practices, and procedures for a safe and efficient air transport network that supports global, social, and economic priorities. As the need to develop aviation security policies and measures arose in the late 1960's, ICAO developed enhanced, uniform security measures, policies, and guidelines to address any acts of unlawful interference within the aviation system. All security initiatives placed by ICAO rely on the cooperation and commitment among member states.

To make advances in environmental stewardship, ICAO has developed additional standards, policies, and guidance material to specifically address aircraft noise and engine emissions. Most of ICAO's work within the environmental field is undertaken by the ICAO Committee on Aviation Environmental Protection (CAEP), including the collection of aircraft exhaust data from engine manufacturers for engines that have entered production. Many of these engines are used on military aircraft found at DAF bases and are often given a military designation to differentiate them from their civilian engine counterparts. Military-sponsored emissions tests have not been conducted on these engines and EFs have not been developed for them. The data

collected by CAEP may be utilized to assist in the calculation of aircraft engine emissions. This document includes EFs that have been developed from various studies as well as those provided by ICAO. This section of the document serves to briefly describe how the ICAO EFs were calculated so they may be used to calculate emissions from aircraft flight operations.

The aircraft exhaust data gathered by CAEP has been standardized per engine based on percent engine thrust. These values are used with the emission data sheets provided by ICAO to calculate aircraft engine emissions. ICAO emissions data sheets provide NO_x and CO emission indices, but do not provide VOC or PM emission indices directly. ICAO provides hydrocarbon (HC) emission indices which are multiplied by a scaling factor of 1.15 to estimate VOCs. This scaling factor is provided by a combined FAA and EPA report titled *Recommended Best Practice for Quantifying Speciated Organic Gas Emissions from Aircraft Equipped with Turbofan, Turbojet, and Turboprop Engines* (May 2009).

ICAO does not directly provide PM emissions, but describes three types of PM, and outlines a method to calculate each. The first type of PM consists mainly of black carbon and is designated as non-volatile (EI(PM)_{nv}). The second type of PM is designated volatile sulfate (EI(PM)_{vol-FSC}) and is dependent on the sulfur content of the fuel burned in the engine. The last type of PM is designated organic volatiles (EI(PM)_{vol-FuelOrganics}) and results from the incomplete combustion of fuel. The sum of these three values is assumed to represent PM₁₀, with PM_{2.5} assumed to equal 90% of the PM₁₀ total.

When calculating the non-volatile portion of the PM emissions indices, the first step is to verify that a smoke number (SN), which acts as a surrogate or indicator of plume opacity, has been provided for each mode. If not, the *ICAO Airport Air Quality Manual* may be consulted to estimate those SNs that are missing. Next, calculate the carbon index, which is “a measure of the black carbon mass per standard volume of flow” (ICAO 2011). Depending on the value of the SN, two different equations are used to calculate Carbon Index. For those SNs less than or equal to 30, the first equation is used, while the second is used for those SNs greater than 30.

$$CI = 0.06949(SN)^{1.234} \quad SN \leq 30$$

$$CI = 0.0297(SN)^2 - 1.803(SN) + 31.94 \quad SN > 30$$

Where,

CI = Carbon Index (mg/m³)

SN = Smoke Number

The volumetric flow rate (Q_{Core} or Q_{Mixed}) is calculated according to the engine type reported on the ICAO data sheet, or in the database. For engines listed as turbofan (TF), Q_{Core} is calculated using the first equation below. For those listed as mixed turbofan (MTF), Q_{Mixed} may be calculated using the second equation. The Air-Fuel Ratio (AFR) used in calculations is usually

proprietary information, but ICAO has developed average AFR values that may be used, which are provided in the *ICAO Airport Air Quality Manual* (ICAO 2011).

$$Q_{Core} = 0.776(AFR) + 0.877 \quad \text{For Turbofan Engines}$$

$$Q_{Mixed} = 0.7769(AFR)(1 + BPR) + 0.877 \quad \text{For Mixed Turbofan Engines}$$

Where,

Q_{Core}	=	Volumetric flow rate for TF engine (m ³ /kg)
Q_{Mixed}	=	Volumetric flow rate for MTF engine (m ³ /kg)
AFR	=	Air-fuel ratio as given in ICAO
BPR	=	Bypass Ratio as provided on ICAO datasheet or in ICAO database

Finally, the emission index (EI) for non-volatile PM (EI(PM)_{nv}) is calculated by multiplying the Carbon Index by the volumetric flow rate as shown below.

$$EI(PM)_{nv} = CI \times Q$$

Where,

EI(PM)_{nv}	=	Emission Index for non-volatile PM (mg/kg)
Q	=	Volumetric flow rate; either Q _{Core} or Q _{Mixed}

The volatile PM sulfate portion of the PM emission index (EI(PM)_{vol-FSC}) is a function of the fuel sulfur content and the fuel sulfur conversion efficiency. If the sulfur content is unknown, the national average weight percent as given in Table 2-2 may be used in the calculations. Similarly, if the fuel sulfur conversion efficiency is unknown, ICAO recommends that a median value of 2.4 wt.% be used. The following equation is used to determine EI(PM)_{vol-FSC}.

$$EI(PM)_{vol-FSC} = (10)^6 \times \left[\frac{(FSC/100) \times (\epsilon/100) \times 96}{32} \right]$$

Where,

EI(PM)_{vol-FSC}	=	Emission index for volatile sulfate PM (mg/kg)
FSC	=	Fuel sulfur content. Use Table 2-2 if unknown (%)
(10)⁶	=	Factor for converting units to mg/kg
100	=	Factor converting percent to a fraction (%)
ε	=	Fuel sulfur conversion efficiency. Use 2.4 if unknown (%)
96	=	Molecular weight of sulfate (g/mol)
32	=	Molecular weight of sulfur (g/mol)

Finally, the organic volatiles (EI(PM)_{vol-FuelOrganics}) portion of the PM EI is calculated by taking the product of the HC EI and the ratio of EI(PM)_{vol-FuelOrganics} to the HC EI of a reference engine. ICAO uses the CFM56-2-C1 as the reference engine for this ratio. The calculation of EI(PM)_{vol-FuelOrganics} is shown in the following equation:

$$EI(PM)_{vol-FuelOrganics} = \delta \times EI_{HC}$$

Where,

EI(PM)_{vol-FuelOrganics}	=	Emission index for PM from fuel organics (mg/kg)
δ	=	Ratio of EI _{PMvol-FuelOrganics} to EI _{HC} for the CFM56-2-C1 engine
EI_{HC}	=	Hydrocarbon emission index of the engine

After EI(PM)_{nvol}, EI(PM)_{vol-FSC}, and EI(PM)_{vol-FuelOrganics} are calculated, the emission index for PM₁₀ is estimated by summing these values and converting into the correct units as shown:

$$EI(PM_{10}) = \frac{[EI(PM)_{nvol} + EI(PM)_{vol-FSC} + EI(PM)_{vol-FuelOrganics}]}{1000}$$

Where,

EI(PM₁₀)	=	Emission index for PM ₁₀ (g/kg)
EI(PM)_{nvol}	=	Emission index for non-volatile PM (mg/kg)
EI(PM)_{vol-FSC}	=	Emission index for volatile sulfate PM (mg/kg)
EI(PM)_{vol-FuelOrganics}	=	Emission index for volatile fuel organic PM (mg/kg)
1000	=	Factor to convert units from mg to g (mg/g)

PM_{2.5} may then be determined from PM₁₀ by assuming PM_{2.5} is equal to 90% of the PM₁₀ value.

$$EI(PM_{2.5}) = EI(PM_{10}) \times 0.90$$

Where,

EI(PM_{2.5})	=	Emission index for PM _{2.5} (g/kg)
EI(PM₁₀)	=	Emission index for PM ₁₀ (g/kg)
0.90	=	Fraction of total PM _{2.5} to PM ₁₀

EFs have been calculated using ICAO data for engines that are most likely to be found at DAF installations. These have been added to EFs that have already been developed from government-subsidized studies. For any engine without a listed EF, if ICAO emissions data is available, the EFs may be calculated as described in this section as needed.

2.7 Information Resources

The Flightline Operations Group and aircraft pilots should be contacted to obtain the information required to calculate emissions from aircraft flying operations (i.e., the number of LTOs, TGOs, LFBs, TIM, etc.). The Aircraft Maintenance Squadron (AMX) should be contacted to obtain the information needed to calculate emissions from on-wing engine testing operations. This includes the types of engines tested, the number of tests conducted during the year on each engine type, the average time spent at each power setting during a typical test, and the associated fuel flow rate at each power setting. Additionally, the base's Weather Department should be contacted to

obtain the average mixing zone height for the base.

2.8 Example Calculations

The following section provides example calculations for aircraft operations.

2.8.1 Problem 1 – Landing and Takeoff Cycle Emissions

For planning purposes, a DAF installation needs to calculate the annual CO emissions from LTO operations associated with their F-15D aircraft. The following information was obtained from the base:

Aircraft Model: F-15D
 Engine Model: F100-PW-220
 Number of Engines: 2
 Number of Annual LTOs: 2,500

Given this is only for planning purposes, the TIM data from Table 2-5 and the mode-specific fuel flow rates and EFs from Table 2-9 for the F100-PW-220 engine are presented in the following table:

LTO Mode	Average TIM (min.)	Typical Power Setting	Average Fuel Flow Rate (lb/hr)	CO Emission Factor (lb/1000 lb fuel)
Taxi/Idle-out	18.50	Idle	2,084	35.32
Takeoff	0.40*	Military	9,679	0.86
		Afterburner	41,682	11.87
Climb out	0.80	Intermediate	5,770	0.86
Approach	3.50	Approach	3,837	1.92
Taxi/Idle-in	11.30	Idle	2,084	35.32

* Since this engine has afterburner capability, it is assumed that the duration of the Takeoff mode is 50% Afterburner and 50% Military.

The annual CO emissions from F-15D LTO cycles are calculated using Equation 2-1 as shown:

$$E(Pol)_{Aircraft} = \sum_{i=1}^n \left[\frac{TIM_i}{60} \times \frac{FFR_i}{1,000} \times EF(Pol)_i \times \frac{FERF(Pol)}{100} \right] \times N$$

Step 1 – Calculate CO pollutant emissions for each engine in each mode in the LTO cycle.

$$E(Pol)_{mode} = \frac{TIM_i}{60} \times \frac{FFR_i}{1,000} \times EF(Pol)_i \times \frac{FERF(Pol)}{100}$$

$$E(CO)_{Idle-Out} = \frac{18.50}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{2084}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 35.32 \frac{lb}{\cancel{10^3 lb fuel}} = 22.7 \frac{lb}{cycle}$$

$$E(CO)_{Approach} = \frac{3.50}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{3837}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 1.92 \frac{lb}{\cancel{10^3 lb fuel}} = 0.43 \frac{lb}{cycle}$$

$$E(CO)_{Takeoff(Mil)} = \frac{0.20}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{9679}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 0.86 \frac{lb}{\cancel{10^3 lb fuel}} = 0.03 \frac{lb}{cycle}$$

$$E(CO)_{Takeoff(AB)} = \frac{0.20}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{41682}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 11.87 \frac{lb}{\cancel{10^3 lb fuel}} = 1.65 \frac{lb}{cycle}$$

$$E(CO)_{Climb out} = \frac{0.80}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{5770}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 0.86 \frac{lb}{\cancel{10^3 lb fuel}} = 0.07 \frac{lb}{cycle}$$

$$E(CO)_{Idle-in} = \frac{11.30}{60} \frac{\cancel{min}/cycle}{\cancel{min}/hr} \times \frac{2084}{1,000} \frac{\cancel{lb}/hr}{\cancel{lb}/10^3 lb} \times 35.32 \frac{lb}{\cancel{10^3 lb fuel}} = 13.86 \frac{lb}{cycle}$$

Step 2 – Calculate the total CO emissions for a single F-15D LTO.

$$E(Pol)_{LTO} = \sum_{i=1}^n [E(Pol)_{Mode_i} + \dots + E(Pol)_{Mode_n}] \times 2$$

$$E(CO)_{LTO} = (22.7 + 0.43 + 0.03 + 1.65 + 0.07 + 13.86) \frac{lb}{cycle} \times 2 = 77.48 \frac{lb}{cycle}$$

Step 3 – Determine the total CO emissions from annual F-15D operations.

$$E(CO)_{Aircraft} = 77.48 \frac{lb}{cycle} \times 2500 \frac{cycle}{yr}$$

$$E(CO)_{Total} = 193,700 \frac{lb}{yr}$$

2.8.2 Problem 2 – Auxiliary Power Unit Emissions

For planning purposes, a DAF installation also needs to calculate the annual NO_x emissions associated with the operation of the APUs on their aircraft. The following information was obtained:

APU Model	GTCP165-1
# APU per aircraft	1
Power Setting	Constant
Operating Time per LTO	15 minutes
Total LTO per year	1300

The annual NO_x emissions from APU use is calculated using Equation 2-2 as shown:

$$E(Pol)_{APU} = L \times N \times \frac{OT}{60} \times EF(Pol) \times \frac{FERF}{100}$$

Step 1 – Calculate the NO_x emissions for a single LTO cycle. Note that Table 2-12 lists the NO_x EF for the GTCP165-1 as **1.22 lb/hr**.

$$E(NO_x)_{LTO} = \frac{15(\cancel{\text{min}}/\text{cycle})}{60(\cancel{\text{min}}/\text{hr})} \times 1.22 \left(\frac{\text{lb}}{\text{hr}} \right) = 0.305 \frac{\text{lb}}{\text{cycle}}$$

Step 2 – Calculate the NO_x pollutant emissions from annual APU operations.

$$E(Pol)_{APU} = L \times N \times E(Pol)_{LTO}$$

$$E(NO_x)_{APU} = 1300 \left(\frac{\text{cycle}}{\text{yr}} \right) \times 1 \times 0.305 \left(\frac{\text{lb}}{\text{cycle}} \right)$$

$$E(NO_x)_{APU} = 396.5 \frac{\text{lb}}{\text{yr}}$$

2.8.3 Problem 3 – On-Wing Engine Testing

A DAF installation performs on-wing evaluations of the F110-GE-100 engines used on their F-16D aircraft. The base must calculate CO and SO_x emissions from on-wing testing operations. The base and the fuel supplier are in Louisiana, and the base wants the SO_x emissions specific for Louisiana sulfur content. Approximately 30 on-wing engine tests following similar procedures were conducted during the year. For these similar on-wing tests, the procedure, average fuel flow rate (FFR), and average operating times are summarized as follows:

Procedure	Avg FFR (lb/hr)	Avg Operating Time (min)
Stabilize at Idle	809.33	5
Accelerate and Hold	4,147.78	5
Stabilize at Idle	981.21	1

Accelerate and Hold	8,170.88	5
Decelerate and Hold	1,232.67	5
Accelerate and Hold	12,223.02	2
Decelerate and Hold	1,187.40	2
Accelerate and Hold	17,959.14	0.25
Decelerate and Hold	2,201.55	2
Stabilize at Idle	1,205.45	5
Shut down engine	---	---

Step 1 – Determine the engine power mode for each test setting. The operating mode encompasses a range of fuel flow rates. Select the operating mode by finding where the average fuel flow rate in the table above falls within the fuel flow rate range for the operating mode. Typically, this is simply by finding the numerically closest fuel flow rate in Table 2-9 to the average rates recorded in the table above, however, refer to the appropriate tables for the latest version of the *Air Emissions Guide for Air Force Stationary Sources* for assistance as needed. The operating modes are as follows:

Procedure	Avg FFR (lb/hr)	Avg Operating Time (min)	Engine Power Mode
Stabilize at Idle	809.33	5	Idle
Accelerate and Hold	4,147.78	5	Approach
Stabilize at Idle	981.21	1	Idle
Accelerate and Hold	8,170.88	5	Intermediate
Decelerate and Hold	1,232.67	5	Idle
Accelerate and Hold	12,223.02	2	Military
Decelerate and Hold	1,187.40	2	Idle
Accelerate and Hold	17,959.14	0.25	Afterburner
Decelerate and Hold	2,201.55	2	Idle
Stabilize at Idle	1,205.45	5	Idle

Step 2 – Calculate CO and SO_x emissions for each operating mode. In this example, calculating the emissions while operating in the “idle” modes is the most complicated since the engine is tested in that mode at several points and at different fuel flow rates. Note also that this example states that the base conducted 30 “similar” tests, and without calculating emissions using data from each test, the following method is an approximation. It is up to the base to determine the level of precision required when estimating emissions from on-wing engine testing. The emission factors for CO and SO_x for fuel flow rates corresponding to a flight mode are provided in Table 2-9.

$$E(Pol)_{mode} = \sum_{i=1}^n \left[\frac{TIM_i}{60} \times \frac{FFR_i}{1000} \times EF(Pol)_i \times \frac{FERF(Pol)}{100} \right]$$

$$E(CO)_{Idle} = \left[\left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{809.33 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{1 \text{ min/test}}{60 \text{ min/hr}} \times \frac{981.21 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1232.67 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{2 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1187.40 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{2 \text{ min/test}}{60 \text{ min/hr}} \times \frac{2201.55 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1205.45 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) \right] \times 24.11 \frac{\text{lb}}{10^3 \text{ lb fuel}} \times 30 \frac{\text{tests}}{\text{yr}} = 289.28 \frac{\text{lb}}{\text{yr}}$$

$$E(SO_x)_{Idle} = \left[\left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{809.33 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{1 \text{ min/test}}{60 \text{ min/hr}} \times \frac{981.21 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1232.67 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{2 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1187.40 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{2 \text{ min/test}}{60 \text{ min/hr}} \times \frac{2201.55 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) + \left(\frac{5 \text{ min/test}}{60 \text{ min/hr}} \times \frac{1205.45 \text{ lb/hr}}{1000 \text{ lb}/10^3 \text{ lb}} \right) \right] \times 1.07 \frac{\text{lb}}{10^3 \text{ lb fuel}} \times 30 \frac{\text{tests}}{\text{yr}} = 12.84 \frac{\text{lb}}{\text{yr}}$$

CO and SO_x emissions for other modes are similarly calculated and is summarized as follows:

Mode	CO Emissions (min lb fuel lb/hr 10 ³ lb fuel yr)	SO _x Emissions (min lb fuel lb/hr 10 ³ lb fuel yr)
Idle	289.28	12.84
Approach	59.83	11.10
Intermediate	70.88	21.86
Military	41.31	13.08
Afterburner	151.33	2.40

Step 3 – Determine the total CO and SO_x emissions.

$$E(Pol)_{Aircraft} = \sum_{i=1}^n E(POL)_{Mode}$$

$$E(CO)_{Aircraft} = (289.28 + 59.83 + 70.88 + 41.31 + 151.33) \left(\frac{\text{lb}}{\text{yr}} \right)$$

$$E(CO)_{Aircraft} = 612.63 \frac{\text{lb}}{\text{yr}}$$

$$E(SO_x)_{Aircraft} = (12.84 + 11.10 + 21.86 + 13.08 + 2.40) \left(\frac{\text{lb}}{\text{yr}} \right)$$

$$E(SO_x)_{Aircraft} = 61.27 \frac{lb}{yr}$$

Note that the *Air Emissions Guide for Air Force Stationary Sources* provides an example of how to estimate emissions for jet engine testing. The two examples show a slightly different but virtually identical method for estimating emissions from both processes.

2.8.4 Problem 4 – Flight Cycle Emissions

For planning purposes, an AFB is receiving ten new Sikorsky Black Hawks (UH-60) that will perform 1,000 flight cycles annually. The UH-60 is equipped with two T700-GE-700 engines. Given the time spent in each phase given below, determine the total annual NO_x emissions from this action.

Idle TIP (TIP_{Idle}) = 5.5 min

Site-specific taxi time (TIP_{Taxi}) = 7.6 min

Takeoff TIP (TIP_{Takeoff}) = Landing TIP (TIP_{Landing}) = 0.68 min

Flight TIP (TIP_{Flight}) = 7.45 min

Step 1 – Determine the FFR and NO_x EF for each flight phase. This data is provided in Table 2-7 and provided in the table below:

Flight Phase	Fuel Flow (lb/hr)	Emission Factor (lb/1,000 lb fuel)						
		NO _x	SO _x	CO	VOC	HAPs	PM ₁₀	PM _{2.5}
Idle	134	3.36	1.07	46.24	0.50	0.33	1.48	1.33
Taxi	469	10.95	1.07	5.12	0.02	0.01	1.26	1.13
Takeoff or Landing	626	11.87	1.07	3.51	0.01	0.00	2.22	2.00
Flight	725	11.43	1.07	2.81	0.01	0.01	2.61	2.33

Step 2 – Calculate the total NO_x emissions. Using Equation 2-4 and the data provided above, the total NO_x emissions are calculated as follows:

$$E(Pol) = \sum_{i=1}^n \left[\frac{TIP_i}{60} \times \frac{FFR_i}{1000} \times EF(Pol)_i \right] \times N \times C$$

$$E(NO_x) = \sum \left[\left(\frac{5.5 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \times \frac{134 \frac{\text{lb}}{\text{hr}}}{1000 \frac{\text{lb}}{10^3 \text{ lb}}} \times 3.36 \frac{\text{lb}}{10^3 \text{ lb}} \right) + \left(\frac{7.6 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \times \frac{469 \frac{\text{lb}}{\text{hr}}}{1000 \frac{\text{lb}}{10^3 \text{ lb}}} \times 10.95 \frac{\text{lb}}{10^3 \text{ lb}} \right) + \left(\frac{0.68 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \times \frac{626 \frac{\text{lb}}{\text{hr}}}{1000 \frac{\text{lb}}{10^3 \text{ lb}}} \times 11.87 \frac{\text{lb}}{10^3 \text{ lb}} \right) + \left(\frac{0.68 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \times \frac{626 \frac{\text{lb}}{\text{hr}}}{1000 \frac{\text{lb}}{10^3 \text{ lb}}} \times 11.87 \frac{\text{lb}}{10^3 \text{ lb}} \right) + \left(\frac{7.45 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \times \frac{725 \frac{\text{lb}}{\text{hr}}}{1000 \frac{\text{lb}}{10^3 \text{ lb}}} \times 11.43 \frac{\text{lb}}{10^3 \text{ lb}} \right) \right] \times 2 \times \frac{1000}{yr}$$

$$E(NO_x) = \sum[(0.04 \text{ lb}) + (0.65 \text{ lb}) + (0.08 \text{ lb}) + (0.08 \text{ lb}) + (1.03 \text{ lb})] \times 2 \times \frac{1000}{\text{yr}}$$

$$\boxed{E(NO_x) = 3,760 \frac{\text{lb}}{\text{yr}}}$$

Table 2-4. Comparison of Commercial and Military Fixed-Wing LTO Cycle Modes

Engine Type	Commercial LTO Cycle Modes	Military LTO Cycle Modes	Typical Engine Power Setting(%)
Turbofan	Taxi/Idle-out	Idle	7
	Takeoff	Military or Afterburner (AB)	100 or 110-150 ^a
	Climb out	Intermediate	70-85 ^a
	Approach	Approach	30
	Taxi/Idle-in	Idle	7
Turboprop	Taxi/Idle-out	Idle	7
	Takeoff	Military	90
	Climb out	Intermediate	70-85 ^a
	Approach	Approach	30
	Taxi/Idle-in	Idle	7

SOURCE (unless otherwise noted): *Airport Air Quality Manual*, International Civil Aviation Organization, 2011.

- a. Power setting percentage from *Air Emissions Factor Guide to Air Force Mobile Sources*, 2009 which cites Emissions and Dispersion Modeling System (EDMS) as the original source. For military aircraft equipped with afterburner (AB), it should be generally assumed that the duration of Takeoff mode is 50% AB and 50% military.

Table 2-5. Default Time-in-Mode for Various Aircraft Categories

Aircraft Type	Typical Duration by Mode (Minutes)				
	Taxi-in/Taxi-out	Takeoff ^a	Climb out	Approach	Total
Military Aircraft					
Combat:					
USAF	29.80	0.40	0.80	3.50	34.50

Notes for Table 2-6 and Table 2-7 on following page.

Notes for Table 2-6 and Table 2-7.

Note that some Aircraft model/engine/Auxiliary Power Unit (APU) combinations may be missing due to unverified sources and/or missing emission factors for either engine(s) and/or APU(s).

- a. Time-in-Mode category selected for the aircraft based on that aircraft's expected flight pattern and not based on its mission designation.
- b. SOURCE: Flightline Emission Factors – Aircraft/Auxiliary Power Units/Aerospace Ground Support Equipment, IERA-RS-BR-SR-2005-0001, December 2004. This reference cites survey responses as source of data.
- c. This document does not have emission factors for at least one engine/APU listed for this aircraft.
- d. Time-in-Mode category for this aircraft was selected as the recommended category for calculating emissions though this aircraft is operated by another military branch.
- e. APU operating time is an estimate based on similar APUs on similar aircraft.
- f. Aircraft may also be operated as a military helicopter. If the aircraft is primarily operated in this mode at the installation, then use the appropriate Time-in-Mode category.
- g. This aircraft is operated by multiple military branches.
- h. The Airframe/Engine combination source was reported in the following documents:
 - (1) SOURCE: Model Designation of Military Aerospace Vehicles, Department of Defense May 2004.
 - (2) SOURCE: Air Force Reserve Website (www.afreserve.com).
 - (3) SOURCE: Air Pollutant Emission Factors for Military and Civil Aircraft, EPA-450/3-78-117, October 1978.
 - (4) SOURCE: Smithsonian National Air and Space Museum website (www.airandspace.si.edu).
 - (5) SOURCE: Aircraft Engine Emissions Estimator, AFESC, November 1985.
 - (6) SOURCE: US Air Force fact sheets accessed via official Air Force website (www.af.mil).

 - (17) SOURCE: Embraer website (www.embraer.com)
 - (18) SOURCE: Airframe/engine/APU combination and run times collected from field data.
- i. The Airframe/APU combination was reported in the following documents:
 - (1) SOURCE: Air Emissions Factor Guide to Air Force Mobile Sources, AFCEC 2009.
 - (2) SOURCE: EDMS input from Paine Field.
- j. According to the source document, the actual APU operating time may range between 0.23-0.26 if there is gate power or 0.87 if there is no gate power. The most conservative value of 0.87 is listed here.
- k. This engine is not explicitly listed in the source document as the engine in this aircraft. It is listed here, however, because it is an alternate designation of an engine listed in the source document.
- l. This is the military designation of a civilian engine listed for the aircraft in the source document. The source for the military designation of the civilian engine is:
 - (1) SOURCE: Air Force One, Robert F. Dorr, 2002.
 - (2) The Federal Business Opportunities website (www.fbo.gov)

“---” – Indicates either no APU for that aircraft or no data available.

Table 2-8. Commercial Airframe/Engine/APU Combinations

Aircraft Model(s)	Time-In-Mode Category	Engine Model(s) (Number of Engines)	APU Model(s) (Number of APUs)	APU hours of Operation Per LTO ^a [Without Gate Power]	Notes:
A300 Series	Commercial Carrier: Jumbo, long, and medium range jet	CF6-50A, -50C, -50C1, -50C2 (2) CF6-80C2A1, -80C2A3, -80C2A5 (2) JT9D-7R4H1 (2) PW4158 (2)	GTCP 331-250 (1)	0.23 - 0.26 [1.0 - 1.5]	b, c(2), c(3), d(2)

Note that some Aircraft model/engine/APU combinations may be missing due to unverified sources and/or missing emission factors for either engine(s) and/or APU(s).

- SOURCE: *Airport Air Quality Manual*, International Civil Aviation Organization, 2011. ICAO provides a range for both narrow body and wide body aircraft. The values given out of the brackets assume gate power while the bracketed values are in instances where there is no gate power.
- This document does not have emission factors for at least one engine/APU listed for this aircraft.
- The Aircraft/Engine combination source was reported in one of the following documents:
 - SOURCE: *Air Pollutant Emission Factors for Military and Civil Aircraft*, EPA-450/3-78-117, October 1978.
 - SOURCE: The Federal Aviation Administration (FAA) Type Certificate Data Sheet (TCDS) for the airframe model listed.
 - SOURCE: Pratt & Whitney website (www.pw.utc.com).
 - SOURCE: The European Aviation Safety Agency (EASA) TCDS for the airframe model listed.
 - SOURCE: Airbus website (www.airbus.com).
 - SOURCE: Boeing website (www.boeing.com).
 - SOURCE: Tupolev website (www.tupolev.ru/english/).
- Airframe/APU combination source was reported in one of the following:
 - SOURCE: Emissions and Dispersion Modeling System Input from Paine Field
 - SOURCE: FAA TCDS for the listed airframe
 - SOURCE: EASA TCDS for the listed airframe

Notes for Table 2-9:

- a. Power Settings included for both Fixed-wing and Rotary aircraft.
- b. The emission factors for sulfur oxides assumes JP-8 used as the fuel. The value provided is the national average for sulfur content in JP-8, though when conducting an air emissions inventory (AEI), the sulfur content should be obtained directly from the fuel supplier.
- c. The emission factors were found in the following sources:
 - (1) SOURCE: *Air Pollutant Emission Factors for Military and Civil Aircraft*, EPA-450/3-78-117, October 1978.
 - (2) SOURCE: *Airport Air Quality Manual*, International Civil Aviation Organization, 2011 version 24 datasheets.
 - (3) SOURCE: *Aircraft Engine and Auxiliary Power Unit Emissions* Volume I-III, March 1999, IERA-RS-BR-TR-1999-0006.
 - (4) SOURCE: *Aircraft Engine and Auxiliary Power Unit Emissions: Testing Final Report Addendum F119-PW-100* June 2002, IERA-RS-BR-SR-2002-0006.

- d. Surrogate data was used for this engine. The surrogate data was found in the following sources:
 - (1) Data was calculated using values provided in the source document.
 - (2) F100-PW-220
 - (3) F101-GE-102
 - (4) F110-GE-100
 - (5) IO-360-A
 - (6) J52-P-408
 - (7) J57-P-19W
 - (8) J85-GE-13
 - (9) O-320-A2B
 - (10) J85-GE-5A

- (11) PT6A-65
 - (12) R-1820-82
 - (13) TIO-540-A1A
 - (14) LF507-1F
 - (15) PT6A-38
 - (16) PW2040
 - (17) T53-L-13
 - (18) T56-A-15
 - (19) T58-GE-5
 - (20) T64-GE-100
 - (21) TF30-P-7
 - (22) TF34-GE-100A
 - (23) TPE331-3
 - (24) F404-GE-F1D2
 - (25) O-200A
- e. Source document provided emission factors for total hydrocarbons (THC) or non-methane organic gas (NMOG). These values converted to volatile organic compounds (VOCs) using the following equations: $VOC = 1.15 * THC$ or $VOC = NMOG * 0.99$ based on the document *Recommended Best Practice for Quantifying Speciated Organic Gas Emissions from Aircraft Equipped with Turbofan, Turbojet, and Turboprop Engines*, FAA 2009.
 - f. PM data calculated using smoke numbers and the ICAO method. The PM calculated was assumed to be PM_{10} .
 - g. PM reported in the source document was assumed to be PM_{10} .
 - h. $PM_{2.5}$ calculated as 90% of PM_{10} .
 - i. For at least one setting, the emission factors reported are an average of values provided in the source document.
 - j. Percent thrust is an estimate based on tables provided in the source document.
 - k. Fuel used for emission testing:
 - (1) Jet A
 - (2) Jet A-1
 - (3) JP-4
 - (4) JP-5
 - (5) JP-8
 - (6) JP-8+100
 - (7) AVGAS
 - (8) No data on fuel used in tests, assumed to use Kerosene-Type Jet Fuel

“(S)” – Indicates that this emission factor is from a recommended surrogate engine. See note 4 for details.

“(C)” – Indicates that this value was calculated using data provided by the source document.

“---” Indicates No Data Available

Table 2-10. VOC and HAP Emission Factors for Select Engines**F100-PW-100**

"X" Indicates that compound is a HAP.

"—" Indicates No Data Available

ND - Compound not detected at the detection limit. Compound may be present at a value less than the detection limit.

AA - Compound detected was less than the Ambient Air concentration resulting in a negative emission factor when the Ambient Air Concentration was removed.

"X" Indicates that compound is a HAP.

"—" Indicates No Data Available

ND - Compound not detected at the detection limit. Compound may be present at a value less than the detection limit.

AA - Compound detected was less than the Ambient Air concentration resulting in a negative emission factor when the Ambient Air Concentration was removed.

Notes for Table 2-12:

SOURCE (unless otherwise stated): Technical Data to Support FAA's Advisory Circular on Reducing Emissions from Commercial Aviation memorandum. This document states the original source as Proposed Federal Implementation Plan for California, Docket No. A-94-09 memorandum.

- a. SO_x Emission factors assume that JP-8, with an average wt. % of 0.054 Sulfur, is used to power the APU.
- b. Greenhouse Gas (GHG) emission factors are presented in equivalent CO₂ (CO₂e). Original source document provided emission factors for CO₂ and CH₄. CH₄ emissions were then multiplied by the global warming potential (GWP) which is stated as 25 per Table A-1 to Subpart A of 40 CFR 98.

3.0 FLIGHTLINE GROUND SUPPORT EQUIPMENT (AGE)

3.1 Introduction

Most DAF bases operate a variety of Ground Support Equipment (GSE) or Aerospace Ground Equipment (AGE) to support flightline operations and service aircraft. Emissions from AGE or GSE vary by device type, time of operation, and fuel flow rate. For simplicity, both GSE and AGE are generically referred to as GSE in this section. Common examples of military GSE include generators, air conditioners, start carts, heaters, hydraulic test stands, portable light units, air compressors, cargo and bomb lifts, jacking units, aircraft deicers, tractor tugs, and other service equipment. GSE are designed to be mobile so that they can be used at any number of locations on the flightline and can be easily transported to support readiness and deployment activities around the world. Depending on whether the GSE is designed to be self-propelled, it can be categorized as either vehicular or non-vehicular in nature. Although essentially non-road engines, this section addresses emissions from flightline GSE only. Other non-road engines and equipment are addressed separately in this document in the NONROAD ENGINES AND EQUIPMENT (NRDE) chapter. Emissions of concern from the operation of GSE include the criteria pollutants and several HAPs that are commonly associated with fuel combustion processes (including, but not limited to: benzene, naphthalene, and 1,3-butadiene).

GSE operated on a DAF installation are powered by internal combustion engines fueled by JP-8, diesel fuel, motor gasoline (MOGAS), Compressed Natural Gas (CNG), or Liquefied Petroleum Gas (LPG). The process in which fuel ignition occurs in the engine determines whether GSE is categorized as Compression Ignition (CI) or Spark Ignition (SI) in nature. CI GSE include turbine engines fueled with JP-8, and non-turbine engines fueled with diesel. SI GSE may be fueled with MOGAS, CNG, or LPG.

Individual pollutant emissions from each type of GSE are usually calculated using operating time and/or fuel consumption information applied across an operational parameter such as an LTO cycle or over an inventory period (typically one year). Military aircraft and GSE combinations and their associated EF data are provided in Table 3-2. This information was obtained from a survey developed and distributed by Air Force Institute for Operational Health (AFIOH/RSEQ) to various flight squadrons and AGE shops throughout the DAF (Wade 2004). **These aircraft-GSE combinations are provided as a guideline though do not necessarily reflect all potential combinations.** In instances where military GSE information was unavailable, data was obtained from the FAA Emissions and Dispersion Modeling System (EDMS). Common, non-model specific GSE data from EDMS are provided in Table 3-5.

While most DAF GSE is intended to be mobile by design, there may be instances where the regular use of the equipment results in it not being moved at least once in a 12-month

period. Where the GSE is not physically moved during a 12-month consecutive period, or where it is replaced in the same location, by GSE, then the GSE is deemed a stationary source by regulation and must be reviewed for stationary permit requirements. If an air program manager is uncertain whether a piece of GSE should be considered mobile or stationary for regulatory purposes, he/she should coordinate with their Major Command for assistance and consider consulting with the Air Force Regional Environmental Offices to obtain their insight on state-specific requirements as they may apply to GSE.

3.2 Emission Factors

EFs for flightline GSE have been developed through measurement and testing and are provided in a variety of sources. EFs may be model-specific and provided in units of pounds per hour (lb/hr) as provided in Table 3-3, based on the GSE and fuel type as shown in Table 3-6. For equipment that use either diesel or JP-8, the High Heat Value (HHV) of diesel was used for unit conversions where necessary. Diesel's HHV was used because it is higher than JP-8's HHV, and thus conversion will result in more conservative estimates. EFs are selected based on the calculation method as described in the next section.

3.3 Emissions Calculation

Information commonly collected and used to calculate emissions from GSE operations include the type and model of equipment, the operating time, type and volume of fuel consumed, and engine operating load and rated power. There are multiple methods used for calculation of emissions, depending on the available information.

3.3.1 Sortie/LTO Method (Preferred Method)

The Sortie/LTO Method is the Air Force's default method and should be used for all GSE that are included in Table 3-2 and Table 3-3. This method involves applying an EF to the operating time of each GSE during a set period (e.g., an aircraft sortie or LTO cycle, annually, or another inventory period). Emissions using this method are calculated as follows:

$$E(Pol) = OT \times EF(Pol) \times N$$

Equation 3-1

Where,

- E(Pol)** = Emission of each individual pollutant for each piece of GSE (lb/yr)
- EF(Pol)** = Emission factor of each pollutant (lb/hr)
- OT** = Operating time of GSE per sortie (hr/sortie)
- N** = Number of sorties per year (sortie/yr)

The EFs and operating times for calculating emissions for GSE using the sortie/LTO method may be found in the following tables:

- Operating times per sortie/LTO for each GSE and associated aircraft are in Table 3-2.
- EFs for each GSE are found in Table 3-3.

3.3.2 Horsepower/Load Factor Method

The horsepower/load factor method is an alternative method for emissions calculations using the engine's rated hp and typical load factor. The load factor is defined as the ratio of the power an engine draws while in operation to its rated power. To calculate emissions using this method, the rated horsepower, load factor, and operating time for each GSE must be known. Emissions from common, non-model specific GSE may be calculated using the data provided in Table 3-5 and Table 3-6. The following general equation is used:

$$E(Pol) = OT \times \frac{LF}{100} \times hp_{rtd} \times \frac{1}{1000} \times EF(Pol) \times N$$

Equation 3-2

Where,

E(Pol)	= Emissions of each individual pollutant (lb/yr)
OT	= Operating time (hr/unit)
LF	= Load factor (%)
100	= Factor for converting percent to a fraction (%)
hp_{rtd}	= Engine rated hp (hp)
1000	= Factor converting from hp to 10 ³ hp (hp/10 ³ hp)
EF(Pol)	= Emission factor of each pollutant (lb/10 ³ hp-hr)
N	= Number of ground support equipment used each year (units/yr)

Table 3-5 provides average operating loads for many common GSE types, however assuming a load factor of 100% will result in more conservative emissions estimates. Alternatively, the load factor may be calculated according to the following equation if the engine horsepower and horsepower under load are known:

$$LF = \frac{hp}{hp_{rtd}}$$

Equation 3-3

Where,

hp	= Engine horsepower under load (hp)
-----------	-------------------------------------

The EFs and operating times for common GSE needed to calculate emissions using the horsepower/load factor method may be found in the following tables.

- The typical commercial GSE assignments are given in Table 3-4.
- Table 3-5 provides the average rated hp for each GSE.
- EFs for common GSE are provided in a lb/10³ hp-hr basis in Table 3-6.
- Table 3-7 provides EFs for several speciated HAPs for uncontrolled diesel reciprocating internal combustion engines.

3.3.3 Fuel Consumption Method

Another method that can be used to calculate GSE emissions involves multiplying the volume of fuel consumed by an EF that is provided in terms of a mass of pollutant emitted per volume of fuel consumed such as lb/hr or gal/hr. As with the horsepower/load factor method, the fuel consumption method also requires that the user know the operating time for each GSE. The following equation can be used as an alternative method of calculating GSE HAP emissions based exclusively on fuel consumption data:

$$E(Pol) = FC \times \frac{1}{1000} \times EF(Pol) \times N$$

Equation 3-4

Where,

FC = Fuel consumption (gal/unit)

In cases where fuel consumption data is unknown, fuel consumption may be estimated using the operating time and fuel flow rate as shown:

$$FC = OT \times FFR$$

Equation 3-5

Where,

FFR = Fuel flow rate. This may be available from the manufacturer (gal/hr)

Alternatively, fuel consumption may also be estimated using engine and operating parameters including hp (if known), hours of operation, brake-specific-fuel consumption (BSFC) factor, and the heating value of the fuel. The following equation is used:

$$FC = OT \times \frac{(hp \times BSFC)}{HV}$$

Equation 3-6

Where,

BSFC = Brake specific fuel consumption (Btu/hp-hr). **Given in Table 3-1.**

HV = Heating value of the fuel (Btu/gal). **Given in Table 3-1.**

To calculate GSE emissions using the fuel consumption method, the following tables are used:

- Table 3-5 provides typical hp for common GSE.
- Table 3-7 provides the EPAs EFs for HAPs from uncontrolled diesel reciprocating internal combustion engines.

3.3.4 Calculating SO₂ Emissions

A more precise method for estimating SO₂ emissions involves applying fuel flow rate data to derive an SO₂ EF based on pounds of pollutant emitted per hour of operation (lb/hr). There is a conservative assumption that all the sulfur in the fuel is converted to SO₂ during the combustion process. Under this assumption, and with the density and sulfur content values known, a SO₂ EF is calculated using the following equation:

$$EF(SO_2) = FFR \times \rho \times \frac{S}{100} \times 2$$

Equation 3-7

Where,

EF(SO₂) = SO₂ emission factor (lb/hr)

ρ = Density of fuel (lb/gal)

S = Weight percent sulfur content of fuel (%)

100 = Factor for converting a percent to a fraction (%)

2 = Conversion factor which is the ratio of the molecular weight of SO₂ to the molecular weight of S

The value for S typically varies from supplier to supplier and the geographic location where the fuel is produced. For enhanced accuracy of the emissions inventory, the sulfur content and density of the fuel should be obtained from the fuel supplier whenever possible. In the absence of such information, the average density and sulfur content is listed in Table 3-1. The sulfur content of JP-8 varies by region, so if the region-specific sulfur content is required, then refer to Table 2-2.

Table 3-1. Fuel Data

Fuel Type	Heating Value (Btu/unit fuel) ^a	BSFC (Btu/hp-hr) ^b	Density (lb/gal) ^c	Sulfur Content (wt. %) ^c
Diesel	138,000 Btu/gal	8,089	7.14	0.025
MOGAS	125,000 Btu/gal	7,000	6.15	0.018
JP-8	124,000 Btu/gal ^d	---	6.71 ^e	0.054 ^e
LPG	92,000 Btu/gal	10,577 ^f	4.41	Negligible
CNG	1,026 Btu/ft ³	7,858	0.046	0.001

3.3.5 Calculating Emissions from Synthetic Aviation Fuel

On-going DoD and DAF initiatives to reduce dependency on foreign petroleum sources are expected to result in the increased use of non-petroleum fuels in a 50-50 blend with JP-8. Testing and certification of such fuels in aircraft engines indicate the blend reduces PM emissions by an average of 35%, sulfur emissions by 50%, and CO₂ emissions by 1.8% (DAF Research Laboratory 2007). Accordingly, when collecting information on GSE operations, verify the blend percentage and whether synthetic fuel was used. If a 50-50 blend was used, apply the appropriate emission reduction factors as given in Table 2-1.

3.4 Information Resources

The base AGE shop is responsible for the operation and repair of most pieces of GSE. Therefore, they should be able to provide most, if not all, of the information needed to calculate the emissions from the GSE used on the installation. In the absence of base-specific data, default EPA information can be used. In some cases, it may be necessary to contact the GSE manufacturer to obtain necessary information.

3.5 Example Calculations

The following section provides examples of how to calculate emissions from GSE operations using the various methodologies identified above and their associated equations.

3.5.1 Problem 1 – Sortie/LTO Method

A DAF base needs to calculate annual NO_x and xylene emissions from GSE operations associated with their B-1B aircraft. The following information was obtained from the base:

B-1B Aircraft	
GSE Types	A/M32A-86D Generator, A/M32A-95 Start Cart, B-1B AC unit, MJ-40 Bomb lift, NF-2 Light Cart
Sorties/year	200

Step 1 – Record the operating times and NO_x emission factors for each GSE. Since the table above does not provide specific operating times for these GSE, the typical operating times for these GSE may be used. Table 3-2 lists the operating times for the generator as **2.20 hr**, the start cart as **0.50 hr**, the AC unit as **2.40 hr**, the bomb lift as **2.50 hr**, and the light cart as **0.50 hr**. Table 3-3 has the NO_x EFs as **6.102 lb/hr** for the generator, **1.470 lb/hr** for the start cart, **7.659 lb/hr** for the AC unit, **0.340 lb/hr** for the bomb lift, and **0.110 lb/hr** for the light cart.

Step 2 – Calculate annual NO_x emissions for each GSE. Using the information in the table above, the data collected in Step 1, and Equation 3-1, the NO_x emissions for each GSE are calculated as follows:

$$E(Pol) = OT \times EF(Pol) \times N$$

$$E(NO_x)_{A/M32A-86D} = 2.20 \frac{hr}{sortie} \times 6.102 \frac{lb}{hr} \times 200 \frac{sortie}{yr} = 2,684.88 \frac{lb}{yr}$$

$$E(NO_x)_{A/M32A-95} = 0.50 \frac{hr}{sortie} \times 1.470 \frac{lb}{hr} \times 200 \frac{sortie}{yr} = 147.00 \frac{lb}{yr}$$

$$E(NO_x)_{B-1B AC Unit} = 2.40 \frac{hr}{sortie} \times 7.659 \frac{lb}{hr} \times 200 \frac{sortie}{yr} = 3,676.32 \frac{lb}{yr}$$

$$E(NO_x)_{MJ-40} = 2.50 \frac{hr}{sortie} \times 0.340 \frac{lb}{hr} \times 200 \frac{sortie}{yr} = 170.00 \frac{lb}{yr}$$

$$E(NO_x)_{NF-2} = 0.50 \frac{hr}{sortie} \times 0.110 \frac{lb}{hr} \times 200 \frac{sortie}{yr} = 11.00 \frac{lb}{yr}$$

Step 3 – Calculate total NO_x emissions. Sum the emissions from each GSE to get the total NO_x emissions for GSE used for the B-1B.

$$E(NO_X)_{Total} = (2684.88 + 147 + 3676.32 + 170 + 11) \frac{lb}{yr}$$

$$E(NO_X)_{Total} = 6,689.2 \frac{lb}{yr}$$

Next, calculate xylene emissions.

Step 4 – Record the fuel flow rate for each GSE. Table 3-3 shows that the fuel flow rate is **6.47 gal/hr** for the generator and **17.14 gal/hr** for the AC unit. Since the fuel flow rate of the start cart, bomb lift, and light cart are not provided in the table, surrogates must be selected. Ideally, the best surrogates will be similar GSE types with similar hp. For this example, the A/M32A-86D was selected as a surrogate for the A/M32A-95, the elevator loader was selected for the MJ-40, and the generator light cart was selected for the NF-2 light cart. The fuel flow rates for the surrogate equipment are listed as **6.47 gal/hr** for the A/M32A-86D, **6.29 gal/hr** for the elevator loader, and **0.62 gal/hr** for the generator light cart.

Step 5 – Calculate the fuel consumption for each GSE. Use the operating times and fuel flow rates recorded in Step 1 and Step 4 above and Equation 3-5.

$$FC = OT \times FFR$$

$$FC_{A/M32A-86D} = 2.20 \frac{hr}{unit} \times 6.47 \frac{gal}{hr} = 14.23 \frac{gal}{unit}$$

$$FC_{A/M32A-95} = 0.50 \frac{hr}{unit} \times 6.47 \frac{gal}{hr} = 3.24 \frac{gal}{unit}$$

$$FC_{B-1B AC Unit} = 2.40 \frac{hr}{unit} \times 17.14 \frac{gal}{hr} = 41.14 \frac{gal}{unit}$$

$$FC_{MJ-40} = 2.50 \frac{hr}{unit} \times 6.29 \frac{gal}{hr} = 15.73 \frac{gal}{unit}$$

$$FC_{NF-2} = 0.50 \frac{hr}{unit} \times 0.62 \frac{gal}{hr} = 0.31 \frac{gal}{unit}$$

Step 6 – Calculate the total fuel flow rate for GSE. Sum the values calculated in Step 5 as follows:

$$FC_{GSE(Total)} = (14.23 + 3.24 + 41.14 + 15.73 + 0.31) \frac{gal}{unit} = 74.65 \frac{gal}{unit}$$

Step 7 – Record the xylene emission factor. Table 3-7 lists the total xylenes EF as **3.93E-02 lb/10³ gal**.

Step 8 – Calculate xylene emissions. With the estimated fuel consumption calculated in Step 6 and the EF data from Step 7, use Equation 3-4 to calculate xylene emissions:

$$E(Pol) = FC \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(Xylenes) = 74.65 \frac{\text{gal}}{\text{unit}} \times \frac{1}{1000} \left(\frac{10^3 \text{ gal}}{\text{gal}} \right) \times 0.0393 \frac{\text{lb}}{10^3 \text{ gal}} \times 200 \frac{\text{unit}}{\text{yr}}$$

$$E(Xylenes) = 0.587 \frac{\text{lb}}{\text{yr}}$$

3.5.2 Problem 2 – Horsepower/Load Factor Method

A DAF base periodically operates two diesel-powered baggage tractors used to transport the luggage of visiting dignitaries. Using the following information obtained from the base, calculate CO and 1,3-butadiene emissions.

GSE Type – Baggage tractor	
# of GSE	2
Operating Time	15 hr/unit

Step 1 – Record the average rated power and average operating load. This information is provided in Table 3-5. The average rated power is given as **83 hp** and the operating load is shown as **55%**.

Step 2 – Record the emission factors for this GSE for CO and 1,3-butadiene. Table 3-6 gives the EF for CO for diesel baggage tractors as **11.00 lb/10³ hp-hr**. Table 3-7 lists the EF for 1,3-butadiene as **3.16E-04 lb/10³ hp-hr**.

Step 3 – Calculate CO and 1,3-butadiene emissions. Use the data collected in Step 1 and Step 2 with Equation 3-2 to calculate the CO and 1,3-butadiene emissions:

$$E(Pol) = OT \times \frac{LF}{100} \times hp_{rtd} \times \frac{1}{1000} \times EF(Pol) \times N$$

For CO:

$$E(CO)_{Baggage} = 15 \frac{\text{hr}}{\text{unit}} \times \frac{55\%}{100\%} \times 83 \text{ hp} \times \frac{1}{1000} \left(\frac{10^3 \text{ hp}}{\text{hp}} \right) \times 11.00 \frac{\text{lb}}{10^3 \text{ hp-hr}} \times 2 \frac{\text{unit}}{\text{yr}}$$

$$E(CO)_{Baggage} = 15.06 \frac{lb}{yr}$$

For 1,3-Butadiene:

$$E(1,3 - Butadiene)_{Baggage} = 15 \frac{hr}{unit} \times \frac{55\%}{100\%} \times 83 \frac{hp}{unit} \times \frac{1}{1000} \left(\frac{10^3 hp}{hp} \right) \times 0.000316 \frac{lb}{10^3 hp-hr} \times 2 \frac{unit}{yr}$$

$$E(1,3 - Butadiene)_{Baggage} = 4.33E-04 \frac{lb}{yr}$$

3.5.3 Problem 3 – Fuel Consumption Method

A DAF base wants to estimate total toluene emissions for the previous year resulting from the operation of air start units using JP-8. The following information was obtained from the base:

GSE Type – Air Start Units	
GSE Model	A/M32A-95
# of GSE	35
Fuel Consumption	5,000 gal/unit

Step 1 – Record the toluene emission factor. Table 3-7 provides HAP speciation for diesel-fired engines. This table lists the toluene EF as **5.64E-02 lb/10³ gal**.

Step 2 – Calculate the toluene emissions. Use the EF in Step 1, the data from the table above, and Equation 3-4.

$$E(Pol) = FC \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(Toluene) = 5000 \frac{gal}{unit} \times \frac{1}{1000} \left(\frac{10^3 gal}{gal} \right) \times 0.0564 \frac{lb}{10^3 gal} \times 35 \frac{unit}{yr}$$

$$E(Toluene) = 9.87 \frac{lb}{yr}$$

3.5.4 Problem 4 – Estimating SO₂ Emissions

A DAF base has been asked to estimate SO₂ emissions from the operation of its GSE. The following information was obtained from the base:

Equipment Data – GSE	
# of GSE	40
Fuel	JP-8
Fuel Flow Rate	18 gal/hr
Operating time	2 hours

Calculate SO₂ emissions for the AFB which is in the East Central United States.

Step 1 – Record the density and sulfur content of JP-8. Table 3-1 lists the density of JP-8 as **6.71 lb/gal**. Though Table 3-1 also provides the sulfur content, since it is known that the AFB is in the East Central portion of the United States, a more accurate value given in Table 2-2 of Chapter 2 in this document states the sulfur content of JP-8 in that particular region as **0.067%**.

Step 2 – Calculate the SO₂ emission factor. This is accomplished by using Equation 3-7.

$$EF(SO_2) = FFR \times \rho \times \frac{S}{100} \times 2$$

$$EF(SO_2) = 18 \frac{\text{gal}}{\text{hr}} \times 6.71 \frac{\text{lb}}{\text{gal}} \times \frac{0.067\%}{100\%} \times 2 = \mathbf{0.162 \frac{lb}{hr}}$$

Step 3 – Calculate SO₂ emissions. Use the EF calculated in Step 2 and Equation 3-1.

$$E(Pol) = OT \times EF(Pol) \times N$$

$$E(SO_2) = 2 \frac{\text{hr}}{\text{unit}} \times 0.162 \frac{\text{lb}}{\text{hr}} \times 40 \frac{\text{unit}}{\text{yr}}$$

$$\boxed{E(SO_2) = \mathbf{12.96 \frac{lb}{yr}}}$$

Notes for Table 3-2 are provided on the following page.

Notes for Table 3-2:

SOURCE (unless otherwise noted): Data obtained from DAF, IERA-RS-BR-SR-2005-0001, *Flightline Emission Factors – Aircraft/Auxiliary Power Units/Aerospace Ground Support Equipment*, December 2004. Data provided by the DAF flight squadrons and associated AGE shops. When calculating GSE emissions, use the data available at the installation. These aircraft/GSE combinations should be used only in the absence of current, more accurate, data.

- a. Operating time estimated based on operating time of GSE on similar aircraft.
- b. GSE model changed from what was stated in the source document because of suspected error in source.
- c. Cold weather months and cold weather bases only.
- d. Uses GSE assignments for similar, surrogate engine provided in source document.

Note: “Generic” refers to Table 3-2.

“(S)” – Indicates that emission factors for this GSE are not found in this document. In the absence of available data, it is recommended that a similar GSE and associated emission factors be used as a surrogate.

Notes for Table 3-3 are provided on the following page:

Notes for Table 3-3:

- a. Sources of data include the following:
 - (1) Emission factors were obtained from the manufacturer. Fuel usage rates were based on 7,500 Btu/hp-hr.
 - (2) Emission factors were obtained from the Southwest Research Institute report titled *Exhaust Emissions from a DAF A/M32-86D Generator*.
 - (3) Emission factors were obtained from the Pacific Environmental Services report titled *Aerospace Ground Support Equipment Emissions Characterization for Edwards AFB, California*.
 - (4) Emission factors are EPA tier I Non-road engine factors.
 - (5) Emission factors were obtained from *Aircraft/Auxiliary Power Units/Ground Support Equipment Emission Factors*, December 2002
 - (6) Emission factors calculated using the emission factors in Table 3-6 using the hp stated in the table above. If no hp was given, then the average hp for that equipment type was used (Table 3-5). Fuel usage rates were based on 7,500 Btu/hp-hr.
 - (7) Emission factors calculated from on-site emissions testing.
 - b. SO_x emission factor assumes that all sulfur in the fuel reacts to form SO₂. Emission factors calculated using Equation 3-7. Sulfur content and density of the fuels taken from Table 3-1. Where the fuel flow rate was not provided, the appropriate EF was selected from Table 3-6 and multiplied by the horsepower (hp). If no hp was provided, the appropriate value was selected from Table 3-5. For equipment capable of using "Diesel/JP-8", the density and sulfur content of JP-8 were used.
 - c. Emission factors from reference (5) were converted from total hydrocarbons (THC) to VOC by multiplying by a factor of 1.053. Emission factors from reference (7) were converted from total organic gas (TOG) to VOC by multiplying by a factor 1.053 and dividing the result by 1.07. These hydrocarbon conversion factors come from "Conversion Factors for Hydrocarbon Emission Components", U.S. Environmental Protection Agency (EPA), Office of Transportation and Air Quality, July 2010.
 - d. PM_{2.5} conservatively estimated at 97% of PM₁₀ for JP-8 or diesel and 92% of PM₁₀ for gasoline (per *Exhaust and Crankcase Emission Factors for Nonroad Engine Modeling-Compression-Ignition*, EPA420-P-04-009, April 2004).
 - e. CO_{2e} emission factor calculated by taking the product of the default CO₂, CH₄, and N₂O emission factors from Tables C-1 and C-2 of 40 Code of Federal Regulations (CFR) part 98, subpart C and their respective global warming potentials (GWP). The GWP for CO₂, CH₄, and N₂O are 1, 25, and 298, respectively. These values were multiplied by the high heat value of the fuel from Table C-1 of 40 CFR part 98 and the fuel flow rate. In cases where the fuel flow rate was not provided, the product of the EF and GWP were multiplied by the engine hp and brake specific fuel consumption (BSFC). A BSFC value of 8089 Btu/hp-hr was used for the diesel/JP-8 equipment.
 - f. These values were not provided from test data but calculated using the hp (or hp from Table 3-5) and the appropriate emission factor from Table 3-6.
 - g. The source did not provide an EF for this pollutant. The value provided is the average of EF for this pollutant for all ground support equipment.
- “---” Indicates No Data Available.

SOURCE: FAA Emission and Dispersion Modeling System, Version 5.02 for model year 2000 GSE and converted from g/hp-hr to lb/10³ hp-hr.

- Reported as HC in EDMS. All values assumed to be equal to total hydrocarbons (THC) and converted into VOC. For diesel engines, THC was converted to VOC by multiplying THC value by 1.053. All gasoline engines were assumed to be 4-stroke. For gasoline engines, THC was converted to VOC by multiplying the THC value by 0.933. THC values were assumed to equal VOC emissions for CNG and LPG-fired engines. Hydrocarbon conversion factors come from *Conversion Factors for Hydrocarbon Emission Components*, U.S. Environmental Protection Agency (EPA), July 2010.
- Reported as PM in EDMS. All PM assumed to be PM₁₀.
- Using assumptions and factors applied by EPA in its NONROAD model, PM_{2.5} emissions conservatively estimated as 97% of JP-8 or diesel PM₁₀ emissions, 92% of gasoline PM₁₀ emissions, and 100% of CNG or LPG PM₁₀ emissions.
- CO_{2e} is the sum of emission factors for CO₂, CH₄, and N₂O. The emission factors are presented in equivalent CO₂ (CO_{2e}) using global warming potentials of 25 and 298 for CH₄ and N₂O, respectively. The emission factors were provided by the EPA's Emission Factors for Greenhouse Gas Inventories. When "CNG/LPG" is provided as the fuel used, then the greenhouse gas emission factor provided was calculated using the more conservative estimate from LPG. The emission factors for N₂O and CH₄ for CNG and LPG were assumed to be equal to those for gasoline. Calculations were made using the heating values and fuel usage rates provided in Table 3-1.

4.0 NONROAD ENGINES AND EQUIPMENT (NRDE)

4.1 Introduction

Air emissions at DAF installations result not only from military operations, but also from day-to-day activities involving nonroad engines and equipment (NRDE). The full federal definition of a nonroad engine can be found in 40 CFR 1068.30. Examples of NRDE that are commonly operated on DAF installations include: industrial equipment (e.g., forklifts, aerial lifts, sweepers, etc.); lawn and garden equipment (e.g., lawn mowers, trimmers, leaf blowers, snow blowers, etc.); agricultural equipment (e.g., sprayers, agricultural tractors, agricultural mowers, etc.); commercial equipment (e.g., pumps, air compressors, etc.); recreational vehicles (e.g., off-road motorcycles, all-terrain vehicles, including utility vehicles, snowmobiles, golf carts, etc.); and logging equipment (e.g., shredders). Portable generators are nonroad engines but as internal combustion (ICOM) units, their emissions are covered in the appropriate sections of either the *Air Emissions Guide for Air Force Stationary Sources* or *Transitory Sources*. Similarly, AGE and GSE are also nonroad engines that are widely used on DAF installations, but are addressed separately in the “Flightline Ground Support Equipment” section of this Guide. Emissions of concern from the operation of NRDE include criteria pollutants and HAPs associated with fuel combustion processes.

NRDE are typically powered by either a reciprocating internal combustion engine or a small gas turbine. For reciprocating engines, a piston moves inside a cylinder to compress an air/fuel mixture. The air/fuel mixture combusts and expands, pushing the piston through the cylinder. The piston returns, pushing out the exhaust gases, and the cycle is repeated. For gas turbines, ambient air is pressurized with a compressor. Fuel is introduced to this compressed air and is ignited. The high temperature, high pressure air flows through a turbine where it expands, producing shaft energy that is used to drive both the compressor and the electric generator.

Reciprocating engines may differ in design by the diameter of the cylinders in the engine, known as the bore, and the length of the linear movement of the piston in each cylinder, known as the stroke. The size of the engine is related to its displacement per cylinder, which is a measure of the volume of the cylinder multiplied by the length of the stroke. A reciprocating engine may be classified as either 4-stroke or 2-stroke. For a 4-stroke engine, the combustion cycle involves two revolutions of the crankshaft, to which the pistons are connected, and the cycle consists of four stages. The induction stroke occurs when the piston moves down within the cylinder, creating a vacuum and drawing in air or an air/fuel mixture. During the compression stroke, the piston moves up to pressurize the air or air/fuel mixture which then ignites. The heated air expands generating a force on the piston such that it is forced downward again in what is called the power stroke. Finally, the piston moves upward again to force the exhaust gas out of the cylinder during the exhaust stroke and returns to the starting position of the induction stroke so

the cycle may be repeated. 2-stroke engines can operate with just one revolution of the crankshaft because induction of the air or air/fuel mixture occurs concurrently with the release of the exhaust gas.

Detonation of the air/fuel mixture during the compression stroke may occur through either compression or spark ignition (CI or SI). In a CI engine, air is first compressed by the piston in the cylinder, which causes the temperature of the air to rise. Fuel is added to the heated air and combusts due to the temperature of the air being above the auto-ignition temperature of the fuel. Reciprocating CI engines are powered either by diesel fuel or JP-8. SI engines, which use gasoline, natural gas, or LPG differ from CI engines in that the fuel/air mixture does not ignite spontaneously, but rather by a spark. Emissions from nonroad engines will vary due to operating conditions such as temperature, humidity, torque, ignition timing, or even air/fuel mixture. Even slight variations in the air/fuel mixture will dramatically affect pollutant emissions.

While most NRDE are powered by either diesel or gasoline fuel, engines fueled with JP-8 are becoming increasingly more common. Presently, there are few EPA-approved NRDE EFs developed specifically for JP-8. However, since the combustion characteristics between JP-8 and diesel fuel are similar, **emissions from JP-8 fueled NRDE are typically calculated using diesel EFs.**

Gas turbines are composed of three major components: a compressor, a combustor, and a power turbine. In a gas turbine, ambient air is drawn in at the front of the engine with a fan, and the pressure is raised up to 30 times the ambient pressure via a compressor. The compressed air is directed into the combustor section where it is sprayed with fuel and ignited with an electric spark. The burning gases expand, and the high-pressure, high-velocity gas stream passes through a turbine area, driving the movement of an output shaft that converts the energy to useful power. Typically, more than half of the shaft energy produced is needed to drive the internal compressor, with the balance available to drive an external load such as an electric generator or water pump. Gas turbines may be more advantageous than reciprocating engines because of their lower operational cost, lower levels of CO and VOC emissions, and potential for use in cogeneration systems. However, the large initial cost of a gas turbine engine means that they are not likely to be a part of NRDE.

4.2 Emission Factors

Emission factors for NRDE are provided at the end of this section. They have been developed for specific equipment and are in units of lb/10³ hp-hr. The appropriate EF should be selected based on the fuel the engine uses and whether the equipment is a 2-stroke or 4-stroke engine, if applicable. The tables also provide typical load factors and calculated BSFC values which may be needed for emissions calculations as described later in this chapter.

4.2.1 Alternative Fuels and Emissions Reduction

Increasingly stringent regulatory requirements mean that some DAF installations may be encouraged to operate non-road engines and equipment on alternative fuels such as ethanol based E85 (a blend of 85% ethanol and 15% gasoline) or B20 (a blend of 20% biodiesel and 80% petroleum diesel). While there are currently no NRDE that use these alternative fuels, there are on-highway flexible fuel vehicles (FFVs) that can operate on E85 and are required to meet EPA's Tier II vehicle emission standards regardless of the fuel type. Some research suggests evidence of potential emission reduction benefits from the use of E85, although testing has been limited and emissions impacts have not been fully characterized. While some reduction in evaporative emissions is expected due to the displacement of gasoline, emissions are believed to be generally similar to gasoline emissions. Note, however, that data indicates that some HAP emissions are reduced while others are increased. Accordingly, EPA does not support the use of emission reduction factors for engines using E85 fuels.

A somewhat similar situation exists regarding information on the emissions impact of B20 fuels. In October 2002, the EPA issued its technical report on biodiesel emissions (USEPA 2002). This report was developed using various statistical analysis tools to compile and assess the results of 39 studies regarding the impact of B20 use on vehicle emissions. Relative to conventional, on-highway diesel fuel (i.e., conventional low-sulfur diesel with sulfur content < 500 ppm), B20 showed a +2% impact on NO_x emissions, a -10% impact on PM emissions, a -21% impact on HC emissions, and a -11% impact on CO emissions. Since the time of the study, however, ultra-low sulfur diesel (ULSD) regulations limiting the sulfur content of on-highway diesel fuel to 15 ppm have been enacted. Since June 2007, the sulfur content of nonroad diesel fuel has been limited to 500 ppm which was then further reduced to 15 ppm effective June 2010. Another study was conducted under the auspices of the DoD Environmental Security Technology Certification Program (ESTCP). This study sought to measure the impact of B20 on CO, NO_x, PM, HC, and HAP emissions from engines used in on-road and portable power generation applications (Environmental Security Technology Certification Program 2006). Using primarily a B20 biodiesel/ULSD blend, the study showed no significant differences in emissions between the B20 blended with ULSD and the ULSD by itself. No consistent trend was observed with regards to HAP emissions.

These examples indicate that efforts to apply emission reduction factors to estimate emissions from alternatively fueled NRDE should be attempted only after careful review of the most current, validated information available. Information can be obtained from either the EPA, the Department of Energy (DoE), the DoD, and Service Engineering and Research Organizations. Application of the B20 EFs developed by the EPA should only be considered if an installation is confident that the nonroad diesel fuel it is replacing has a sulfur concentration of 500 ppm or less. It is important to note that should the sulfur content exceed 500 ppm, potential emissions

benefits of B20 may be underreported because, to date, emission impacts studies have generally not focused on nonroad engines and fuels.

4.3 Emissions Calculation

This section describes several methodologies available for calculating emissions from nonroad engines and equipment using either the EPA's NONROAD emissions estimating software model, or the underlying EFs in the NONROAD model and manual calculation procedures. Regardless of which approach is chosen, the methodology is applied to each individual piece of NRDE for each pollutant for which emissions are being calculated. The methodologies are briefly described in the following paragraphs.

4.3.1 Emissions Estimation Using the EPA NONROAD Model

The EPA recommends use of its NONROAD modeling software for estimating emissions from the operation of nonroad vehicles and equipment. The software was developed to provide consistent means of generating emissions data required by the CAA. The current NONROAD model predicts emissions of six exhaust pollutants (HC, NO_x, CO, CO₂, SO_x, and PM) for more than 80 basic and 260 specific types of NRDE across a variety of model years that use gasoline, diesel, CNG, or LPG. The model allows PM to be reported as PM₁₀ or PM_{2.5}. **As of June 2014, the NONROAD model was integrated into the Motor Vehicle Emissions Simulator (MOVES 2014) model as an additional module and can now be run within the MOVES software. On August 2023, the MOVES4 model became the official version of MOVES, which continues to include and support the NONROAD model.**

A major benefit of the NONROAD model is that it recognizes that an engine's performance degrades over time due to normal operation and use. Engine deterioration not only increases exhaust emissions, but usually leads to a loss of combustion efficiency, and may increase non-exhaust emissions. EPA believes there is insufficient information to justify the use of adjustment factors for small SI engines. Therefore, the NONROAD model uses EFs based on unadjusted steady-state test results, and applies an adjustment factor only to SI engines with a power rating greater than 25 hp. In terms of CI engines, the NONROAD model addresses the effects of deterioration by multiplying a zero-hour EF for each category of engine by a deterioration factor to reflect degraded performance as the engine ages.

While the core model for NONROAD is written in FORTRAN and can be operated as a standalone application in a DOS environment, the graphical user interface will generate scenarios for only one specified set of conditions. If the user requires multiple scenarios in a single model run, the scenarios must be generated in a DOS environment. The NONROAD reporting utility is written in Microsoft Access and operated similarly to the graphical user

interface. The reporting utility is a standalone application and knowledge of Access is not required to generate reports.

EFs for NRDE manufactured prior to Model Year 1998 have been derived from the NONROAD model and its underlying data sets by the EPA Office of Transportation Air Quality. EFs are provided in Table 4-1 through Table 4-5 and serve as the basis for estimating emissions manually using the methodologies discussed in the following subsections.

4.3.2 Horsepower/Load Factor Method

The most common approach for calculating emissions from NRDE is essentially the same as the method incorporated into the NONROAD model and the horsepower/load factor method used in the “FLIGHTLINE GROUND SUPPORT EQUIPMENT (AGE)” section. Emissions are estimated based on the engine’s rated power output, a load factor, and annual operating time. Generally, for calculating emissions from non-road engines, a load factor of 100% is assumed and used in the following equation:

$$E(Pol) = OT \times \frac{LF}{100} \times hp_{rtd} \times \frac{1}{1000} \times EF(Pol) \times N$$

Equation 4-1

Where,

- E(Pol)** = Annual emissions of each individual pollutant (lb/yr)
- OT** = Operating time (hr/unit)
- LF** = Load factor (%). Typically assumed to be 100%, though it may be calculated using Equation 3-3 in this guide.
- 100** = Factor for converting percent to a fraction (%)
- hp_{rtd}** = Engine rated horsepower (hp)
- 1000** = Factor converting from hp to 10³ hp (hp/10³ hp)
- EF(Pol)** = Emission factor of each pollutant (lb/10³ hp-hr)
- N** = Number of nonroad engines and equipment used each year (units/yr)

The data required for calculating emissions using the horsepower/load factor method may be found in Table 4-1 through Table 4-5.

4.3.3 Fuel Consumption Method

Estimating emissions based on fuel consumption can be utilized in instances when the fuel consumption is known but the operating time of the NRDE is not. The annual fuel consumption, fuel density, BSFC values for the piece of equipment, and EF must be known to calculate emissions using this method as illustrated in the equation below:

$$E(Pol) = \frac{(FC \times \rho)}{BSFC} \times EF(Pol) \times N$$

Equation 4-2

Where,

- E(Pol)** = Annual emissions of each individual pollutant (lb/yr)
- FC** = Annual fuel consumption (gal/unit). If the total fuel consumed is unknown, the fuel consumed may be calculated using Equation 3-5 or Equation 3-6
- ρ** = Fuel density (lb/gal)
- BSFC** = Brake-specific fuel consumption for the engine (lb/10³ hp-hr)
- EF(Pol)** = Emission factor for each pollutant (lb/10³ hp-hr)
- N** = Number of equipment used each year (units/yr)

When performing emissions calculations using the fuel consumption method, enhanced accuracy may be achieved by using the density of the fuel as provided by the fuel supplier, and the BSFC for the engine provided directly from the engine manufacturer. If this data is unavailable, then suggested values for these variables may be found in the following tables:

- Table 3-1 provides the average density for nonroad fuels.
- Table 4-1 through Table 4-6 provides the EFs and BSFC for specific equipment types in lb/10³ hp-hr.

4.3.4 VOC and HAP Speciation

There is little data available for the speciation of VOCs for nonroad engines. Whenever the quantity of speciated compounds is required to be calculated, the average percentage of each species within the total VOC may be used as a gross estimate of the emissions of that compound. This section should only be used if no acceptable speciated EFs are available for the engine in question. Speciated VOCs are calculated by taking the product of the total VOCs and the weighted percentage of the individual VOC as follows:

$$E(Pol) = E(VOC) \times \frac{P(Pol)}{100}$$

Equation 4-3

Where,

- E(Pol)** = Emissions of speciated VOC (lb/yr)
- E(VOC)** = Emissions of total VOC (lb/yr)
- P(Pol)** = Weight percent of a given pollutant (%). These are provided in Table 4-7
- 100** = Factor for converting percent to a fraction (%)

The weight percent of individual pollutants were calculated for engines combusting diesel, gasoline, natural gas (which is further subdivided into 2- and 4-stroke lean burn and 4-stroke rich burn), and LPG. The values provided in Table 4-7 were calculated using the equation below. The EF data used in these calculations are from several sources including *Compilation of Air Pollutant Emission Factors* (AP-42), the Mojave Desert Air Quality Management District, and the EPAs *SPECIATE* database. Since the available data regarding mobile NRDE EFs is limited, the factors presented in these sources were assumed to be representative of all non-road engines.

$$P_{(Pol)} = \frac{EF(Pol)}{EF(VOC)_{Total}}$$

Where,

- P(Pol)** = Weight percent of a given pollutant (%)
EF(Pol) = Individual pollutant emission factor (lb/10³ hp-hr)
EF(VOC)_{Total} = Total VOC emission factor (lb/10³ hp-hr)

In addition to the weight percent pollutant speciation values provided in Table 4-7, most equipment manufacturers have data on emissions specific to their product, and many are willing to provide it upon request. HAP emissions may be calculated using the following tables:

- Table 3-7 provides EFs for uncontrolled diesel reciprocating internal combustion engines in a lb/1000 hp-hr format and may be used to calculate HAPs directly using Equation 4-1.
- Table 4-7 gives the weight percent VOC and HAP speciation of emissions for estimating specific VOCs/HAPs using Equation 4-3 above.

4.4 Information Resources

The primary source of information for most NRDE is the Transportation Squadron. The Transportation Vehicle Operations Flight and/or the Transportation Vehicle Maintenance Flight typically maintain records on most DAF-owned NRDE. Records include information such as the identity of the shops/organizations operating the vehicles/equipment, hp rating of the vehicles/equipment, and hours of operation. In some cases, it may be necessary to contact the actual organizations/shops using the vehicle/equipment to obtain information that Transportation may not have. For example, for construction equipment and lawn/garden equipment, it will probably be necessary to contact the Civil Engineering (CE) Operations Flight, the CE Flight and the CE Housing Flight, or a similar organization if base housing has been privatized.

It is important to note that many of the construction and lawn care activities at DAF installations are performed by contractors, and therefore it may be necessary to contact the contractors

directly to obtain the necessary information on their equipment. The contracts section of the CE Engineering Flight should be able to provide information on what equipment was used to perform construction and lawn care activities on base during the year.

In addition, some NRDE (such as leaf blowers, trimmers/edgers, snow blowers, etc.) operated on DAF installations may be owned by personnel who live on base. Since this equipment is privately owned, obtaining this information is usually more difficult than for DAF-owned equipment. One approach to obtaining the necessary information is to work with the CE Housing Flight to identify the types of NRDE used on base housing, estimate the number of each different equipment type, estimate the average hp of each equipment type, and estimate the average operating time (hours per year) for each equipment type. If adequate resources and time are available, a more comprehensive approach would be to survey a representative number of housing units to determine the type and size of equipment used and their associated estimated usage. For NRDE in which emissions are calculated using EFs based on fuel usage (i.e., using “g/gal” EFs), Fuels Supply may be a source of information regarding fuel consumption.

4.5 Example Calculations

The following section provides examples of how the equations and methodologies discussed earlier can be applied to calculate emissions from non-road vehicle and equipment operations. The procedures are applied to each individual NRDE and for each pollutant for which emissions must be calculated. Emissions for all NRDE and pollutants are then summed to obtain the pollutant-specific, base-wide totals. Load factors, BSFCs, and EFs necessary for calculating emissions were obtained from Table 4-1 through Table 4-7.

4.5.1 Problem 1 – Estimating Emissions Using the Horsepower/Load Factor Method

A DAF base has collected information on the NRDE operating on the base for CY 2024. Calculate the CO emissions associated with the operation of diesel-powered forklifts on base. The following information was obtained from the base:

Equipment Type – Diesel powered forklift (SCC-2270003020)	
# of pieces	6
Power Rating	85 hp
Operating Time	200 hr/unit

Step 1 – Record the CO emission factor and load factor. The EF and typical load factor are given in Table 4-1 as **0.269 lb/10³ hp-hr** and **59%** respectively.

Step 2 – Calculate the annual emissions for the six forklifts. Using the information in the table above and the values recorded in Step 1, the annual CO emissions for the six forklifts can be calculated using Equation 4-1:

$$E(Pol) = OT \times \frac{LF}{100} \times hp \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(CO) = 200 \frac{hr}{unit} \times \frac{59\%}{100\%} \times 85(\cancel{hp}) \times \frac{1}{1000} \left(\frac{10^3 \cancel{hp}}{\cancel{hp}} \right) \times 0.269 \frac{lb}{10^3 \cancel{hp-hr}} \times 6 \frac{unit}{yr}$$

$$E(CO) = 16.19 \frac{lb}{yr}$$

4.5.2 Problem 2 – Estimating Emissions Using Fuel Consumption

A DAF base operates gasoline fueled commercial lawn mowers to maintain the appearance of public areas on base. Calculate the VOC and formaldehyde emissions associated with operation of the lawnmowers on base for CY 2022. The following information was obtained from the base:

Equipment Type – 4-stroke gasoline lawnmower (SCC 2265004011)	
# of pieces	25
Power rating	5 hp
Fuel Consumption	40 gal each

Step 1 – Record the fuel density, VOC emission factor, and appropriate BSFC. The fuel density is provided in Table 3-1 and the VOC EF and BSFC value for gas powered commercial lawn mowers are provided in Table 4-1. The fuel density is given as **6.15 lb/gal** while the VOC EF and BSFC (for 2022) are given as **13.997 and 880 lb/10³ hp-hr**, respectively.

Step 2 – Calculate annual VOC emissions. Using the data from Step 1 and Equation 4-2:

$$E(Pol) = \frac{(FC \times D)}{BSFC} \times EF(Pol) \times N$$

$$E(VOC) = \frac{\left(40 \frac{gal}{unit} \times 6.15 \frac{lb}{gal} \right)}{880 \frac{lb}{10^3 \cancel{hp-hr}}} \times 13.997 \frac{lb}{10^3 \cancel{hp-hr}} \times 25 \frac{unit}{yr}$$

$$E(VOC) = 0.2795 \frac{10^3 \cancel{hp-hr}}{unit} \times 13.997 \frac{lb}{10^3 \cancel{hp-hr}} \times 25 \frac{unit}{yr}$$

$$E(VOC) = 97.82 \frac{lb}{yr}$$

Next, calculate formaldehyde emissions.

Step 3 – Record formaldehyde weight percent VOC emissions for 4-stroke gasoline engines.

Table 4-7 lists this value as **1.32%**.

Step 4 – Calculate annual formaldehyde emissions. Using the formaldehyde weight percent recorded in Step 3 and Equation 4-3:

$$E(Pol) = E(VOC) \times \frac{P(Pol)}{100}$$

$$E(Formaldehyde) = 97.82 \frac{lb}{yr} \times \frac{1.32\%}{100\%}$$

$$E(Formaldehyde) = 97.82 \frac{lb}{yr} \times 0.0132$$

$$E(Formaldehyde) = 1.29 \frac{lb}{yr}$$

4.5.3 Problem 3 – Estimating SO_x Emissions

A DAF base needs to estimate SO_x emissions from the operation of rough terrain forklifts. The following information was obtained from the base:

Equipment Data – Rough terrain forklifts (SCC 2270002057)	
# of pieces	5
Fuel	Diesel
Power rating	80 hp
Model year	1997
Fuel Consumption	200 gal (each); 1,000 gal (total)
Hours of operation	250 hr/unit (each)

Since the model year of the forklifts are pre-1998, then the EFs applicable to these engines are found in Table 4-6. The preferred method of using the horsepower and load factor is used for the calculation of emissions.

Step 1 – Record the load factor and SO_x emission factor. According to Table 4-1, for diesel-powered rough terrain forklifts, the typical load factor is **59%** and Table 4-6 lists the SO_x EF as **0.21 lb/10³ hp-hr**.

Step 2 – Calculate the total SO_x emissions. Using these values and the data in the table above, the SO_x emissions can be calculated using Equation 4-1:

$$E(Pol) = OT \times \frac{LF}{100} \times hp \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(SO_x) = 250 \frac{hr}{unit} \times \frac{59\%}{100\%} \times 80 \cancel{hp} \times \frac{1}{1000} \left(\frac{10^3 \cancel{hp}}{\cancel{hp}} \right) \times 0.21 \frac{lb}{10^3 \cancel{hp} \cdot \cancel{hr}} \times 5 \frac{unit}{yr}$$

$$E(SO_x) = 12.39 \frac{lb}{yr}$$

4.5.4 Problem 4 – Estimating Emissions from the Use of B20

A DAF base has been blending B20 biodiesel into the non-road fuel used to power its off-highway trucks. The normal sulfur content of the non-road diesel is 500 ppm. The following information was obtained from the base.

Equipment Data – Off-Highway Trucks (SCC 2270002051)	
# of pieces	10
Fuel	B20/nonroad diesel (500 ppm blend)
Power rating	250 hp
Model year	2001
Hours of operation	200 hours (each); 2,000 hours (total)

Estimate the NO_x and PM₁₀ emissions from the operation of the vehicles.

Step 1 – Record the NO_x emission factor and load factor. Table 4-1 gives the EF and load factor (for 2022) as **3.390 lb/10³ hp-hr** and **59%** respectively.

Step 2 – Calculate annual NO_x emissions. Use the EF and load factor recorded in Step 1, the data provided in the table, and Equation 4-1 as follows:

$$E(Pol) = OT \times \frac{LF}{100} \times hp \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(NO_x) = 200 \frac{hr}{unit} \times \frac{59\%}{100\%} \times 250 \cancel{hp} \times \frac{1}{1000} \left(\frac{10^3 \cancel{hp}}{\cancel{hp}} \right) \times 3.390 \frac{lb}{10^3 \cancel{hp} \cdot \cancel{hr}} \times 10 \frac{unit}{yr} =$$

$$1,000.05 \frac{lb}{yr}$$

Step 3 – Adjust the estimated emissions to reflect the expected 2% increase in NO_x attributable to the use of B20.

$$E(NO_X) = 1,000.05 \frac{lb}{yr} \times \left(1 + \frac{2\%}{100\%}\right)$$

$$E(NO_X) = 1,000.05 \frac{lb}{yr} \times (1.02)$$

$$E(NO_X) = 1,020.05 \frac{lb}{yr}$$

Step 4 – Record the PM₁₀ emission factor. Table 4-1 lists this value as **0.070 lb/10³ hp-hr**.

Step 5 – Calculate annual PM₁₀ emissions. Use Equation 4-1, the EF recorded in Step 4, and the data provided in the table above as follows:

$$E(Pol) = OT \times \frac{LF}{100} \times hp \times \frac{1}{1000} \times EF(Pol) \times N$$

$$E(PM_{10}) = 200 \frac{hr}{unit} \times \frac{59\%}{100\%} \times 250 \cancel{hp} \times \frac{1}{1000} \left(\frac{10^3 \cancel{hp}}{\cancel{hp}} \right) \times 0.070 \frac{lb}{10^3 \cancel{hp-hr}} \times 10 \frac{unit}{yr} = 20.65 \frac{lb}{yr}$$

Step 6 – Adjust the estimated emissions to reflect the expected 10% decrease in PM emissions attributable to the use of B20 fuel:

$$E(PM_{10}) = 20.65 \frac{lb}{yr} \times \left(1 - \frac{10\%}{100\%}\right)$$

$$E(PM_{10}) = 20.65 \frac{lb}{yr} \times (0.9)$$

$$E(PM_{10}) = 18.59 \frac{lb}{yr}$$

Table 4-1. Criteria Pollutant Emission Factors for Non-Road Engines and Equipment – 2023

SCC	Equipment Description	Load Factor ^a (% Max Power)	BSFC ^b (lb/1000 hp-hr)	Emission Factors (lb/1000 hp-hr)

Notes for Table 4-1 through Table 4-5 provided on the following page.

Notes for Table 4-1 through Table 4-5

- a. Load factor and activity data obtained from EPA Office of Transportation Air Quality and were derived from *Median Life, Annual Activity, and Load Factor Values for Nonroad Engine Emissions Modeling*, EPA 420-R-10-016, NR-005d, July 2010.
- b. BSFC and emission factors obtained from EPA Office of Transportation Air Quality and were derived from *Exhaust Emission Factors for Nonroad Engine Modeling: Spark-Ignition*, EPA 420-R-019, NR-010e, December 2005, and *Exhaust Emission Factors for Nonroad Engine Modeling: Compression-Ignition*, EPA 420-P-04-009, NR-009c, April 2004. The emission factors are composite emission factors that represent the national mix of model years and technology types believed to be in existence in 2007. They represent in-use emissions and consider NONROAD model deterioration and transient adjustment factors across all model years.
- c. Activities for off-road motorcycles and all-terrain vehicles are in units of miles per year instead of hours per year.
- d. PM₁₀ is assumed to be equivalent to total PM for gasoline engines.
- e. For gasoline engines, PM_{2.5} is assumed to be 92% of the PM₁₀ value.
- f. For LPG and CNG engines, all PM is assumed to be PM_{2.5}.
- g. The Carbon Dioxide Equivalent (CO₂e) emission factors are the total of CO₂ and CH₄ converted to equivalent CO₂ (CO₂e) using a global warming potential (GWP) value of 25 for CH₄. The converted CH₄ value was added to the CO₂ emission factor and presented as a CO₂e emission factor in units of lb/1000lb. Calculations were made using the stated BSFC, the fuel density in Table 3-1, and if the fuel was not stated, it was assumed to be gasoline. N₂O is not included in these calculations because there is no N₂O pollutant output for the NONROAD module within MOVES4.

Table 4-6. Pre-1998 Non-Road CI Engine Criteria Pollutant Emission Factors (Power Rating > 50 hp)

Equipment Description	Emission Factors (lb/1000 hp-hr)

SOURCE: *Nonroad Engine and Vehicle Emission Study – Report*, EPA 460/3-91-02, 21A-2001, November 1991.

- Reported as hydrocarbon (HC) and converted to VOC by multiplying value by a conversion factor (1.053). This value recommended by the document *Conversion Factors for Hydrocarbon Emission Components*, U.S. Environmental Protection Agency (EPA), Office of Transportation and Air Quality, July 2010.
- Reported as particulate matter (PM) in the source document and assumed to be equal to PM₁₀.
- Assumed to be 97% of PM₁₀ per *Exhaust and Crankshaft Emission Factors for Nonroad Engine Modeling: Compression-Ignition*, EPA 420-P-04-009, April 2004.
- The Greenhouse Gas (GHG) emission factors calculated by summing the product of the emission factors for CO₂, CH₄, and N₂O and their respective global warming potentials (GWP). The GWP for CO₂, CH₄, and N₂O are 1, 25, and 298, respectively. Emission factors for individual GHG calculated by taking the product of the default emission factor provided in Tables C-1 and C-2 of Title 40 Code of Federal Regulations (CFR) Part 98 and the brake-specific fuel consumption (BSFC) for diesel engines provided in Table 3-1.

5.0 ON-ROAD VEHICLES (VEHE)

***Air Force policy considers the dispensing of fuel into on-road vehicles as a mobile source of emissions. However, if the regulator insists this category be included as a stationary source, subtract those emissions from the Mobile AEI and add them to the Stationary AEI to avoid duplicate reporting. This is accomplished by manually calculating emissions generated from on-road vehicle refueling using the procedures given in the “Fuel Dispensing” section of this document, then subtracting those values from the emissions generated by on-road vehicles described in this section. ***

5.1 Introduction

On-road vehicles encompass the full range of passenger cars, light duty trucks, heavy duty trucks, buses, and motorcycles that are specifically designed to operate on highways and other road systems. On-road vehicles in use on DAF installations are classified either as Government Owned Vehicles (GOVs) or Privately Owned Vehicles (POVs). GOVs include all on-road vehicles that are owned or leased and operated by government organizations on the base (e.g., Air Force, Guard, Reserve, etc.). Such vehicles are typically referred to as “fleet vehicles” and range from small passenger cars to large vehicles such as refueling or fire trucks. This classification also includes tactical vehicles. Tactical Vehicles are defined as any motor vehicle designed to military specifications to meet direct transportation support of combat, tactical or relief operations, or for training of personnel for such purposes. POVs are those on-road vehicles that travel on a DAF installation, but are owned or leased and operated by base employees and visitors. Both GOVs and POVs typically operate on conventional gasoline and diesel motor fuels, but may also operate on alternative, non-petroleum-based fuels.

The emissions of concern from the operation of on-road vehicles include the criteria pollutants: NO_x, VOC, CO, SO₂, PM_{2.5}, PM₁₀, and GHGs as well as HAPs. HAPs include: 1,3-butadiene., benzene, acetaldehyde, formaldehyde, acrolein, and methyl tert-butyl ether (MTBE). Some of these direct pollutant emissions also participate in atmospheric reactions that contribute to the formation of ground level ozone and fine PM pollution. Factors which impact the volume of pollutants emitted include the vehicle make and model, the vehicle miles traveled (VMT), the average operating speed, vehicle age, climate, altitude, fuel type and quality, and maintenance procedures. To control vehicle emissions, the EPA has adopted an integrated approach to controlling on-road vehicle emissions. This approach has resulted in the establishment of regulatory standards that consider changes in vehicle and engine design, advanced emission controls, and the mandated use of reformulated and cleaner burning fuels.

Emissions from the operation of on-road vehicles are designated as exhaust, evaporative, or fugitive in nature. Exhaust emissions result from the combustion (sometimes incomplete) of the

motor fuel while evaporative emissions result from the volatilization of the fuel in engine components during the different stages of a vehicle's operating cycle. Additionally, fugitive particulate emissions, in the form of road dust, brake wear dust, and tire wear dust, can be attributed to the operation of on-road vehicles.

The EPA is currently proposing to regulate greenhouse gases (GHGs) for both mobile and stationary sources. As a matter of DAF policy, GHG emissions are to be reported as part of the mobile AEI. Specifically, CO₂, N₂O and CH₄ emissions should be estimated for all mobile sources when EFs are available. Since CO₂, N₂O and CH₄ EFs are attainable for on-road vehicles, emissions should be estimated as part of a mobile source AEI. Additionally, although not currently regulated under the CAA, many regulatory agencies may request installations to include GHG emissions from motor vehicles in mobile source AEIs. Specific requests to calculate and provide CO₂ and/or N₂O and CH₄ emissions data to regulatory agencies as part of this process should be reported through the appropriate Air Force Civil Engineer Center (AFCEC) channels and coordinated through the chain-of-command. Such coordination should be accomplished prior to responding to the request to ensure a consistent DAF response.

Since 1978, the EPA has used computer models to estimate emissions from cars, trucks, and other mobile sources. The EPA's initial on-road vehicle emissions modeling software, known as the MOBILE model, was expanded many times over the years to incorporate new data. The updates kept the basic structure of the model but included new data on vehicle emissions, new vehicle emission standards, and better addressed new policy questions. MOBILE uses average gram per mile emission rates and a series of correction factors to estimate emissions over a wide range of driving conditions. MOBILE6.2, finalized in 2004, was the EPA's official model for highway vehicle emissions. Several analysts have critiqued the MOBILE series of models and suggested that the EPA develop a modeling "toolkit" that would better serve the range of users for highway vehicle modeling, including consistent modeling at the aggregate scale, mesoscale, and microscale analyses.

In response to these and other concerns, the EPA developed the Motor Vehicle Emissions Simulator (MOVES) model. MOVES incorporates extensive new data and advanced algorithms to estimate highway vehicle emissions of GHGs, criteria pollutants, and selected air toxics at the national, regional, and project levels. In September of 2023, the EPA published an announcement in the Federal Register approving the newest model, MOVES4, for official use (outside of California). MOVES4 includes updated vehicle population data, fuel supply, travel activity, and emission rates and incorporates the impacts of the EPA Heavy-Duty low NO_x rule for model years 2027 and later and the light-duty greenhouse gas rule for model years 2023 and later. MOVES4 is used for EPA internal policy analysis and is required for use (outside of California) in the evaluation of State Implementation Plans (SIPs) and transportation conformity determinations. On the official EPA website, use of other models, such as the MOBILE model

and previous versions of MOVES, is being discouraged as they contain outdated or otherwise inaccurate data. The emission factors derived in this guide were generated using the MOVES4 model.

Vehicle emissions within the state of California are not calculated using MOVES software but instead use a similar, California-developed calculation model known as the Emission FACTor (EMFAC) model. On January 15, 2021, California released the latest EMFAC Model, EMFAC2021 and an update was released in April 2022. The EMFAC2021 model was used to derive county emission factors in this guide.

The EPA has historically classified on-road vehicles into eight broad categories based on the motor fuel type and Gross Vehicle Weight (GVW). MOVES was designed to reflect the general fleet distribution or fleet characterization (i.e., fractional vehicle category distribution by year) for a specific location. MOVES can also estimate emission rates (e.g., grams/mile, grams/vehicle) or accept input VMT and vehicle populations to generate total emissions for any year from 1990 and 1999-2050. **The MOVES model incorporates emissions from on-road vehicle refueling. Therefore, these emissions are not addressed in the “Fuel Dispensing” section of this document since they are already accounted for in the EFs presented in this section.**

5.1.1 Vehicle Categories

The 28 vehicle categories from MOVES have been grouped into seven major aggregate categories based on vehicle type and Gross Vehicle Weight Rating (GVWR). Table 5-1 provides the seven major aggregate categories based upon available MOBILE6 EF outputs and readily identifiable general vehicle groupings. The seven aggregate vehicle categories are:

- ***Light-Duty Gasoline Vehicles (LDGV)*** – All gasoline-powered passenger cars
- ***Light-Duty Diesel Vehicles (LDDV)*** – All diesel-powered passenger cars
- ***Light-Duty Gasoline Trucks (LDGT)*** – All smaller gasoline-powered trucks (0 to 8,500 lbs. GVWR)
- ***Light-Duty Diesel Trucks (LDDT)*** – All smaller diesel-powered trucks (0 to 8,500 lbs. GVWR)
- ***Heavy-Duty Gasoline Vehicles (HDGV)*** – All larger gasoline-powered vehicles (8,501 lbs. to >60,000 lbs. GVWR)
- ***Heavy-Duty Diesel Vehicles (HDDV)*** – All larger diesel-powered vehicles (10,001 lbs. to > 60,000 lbs. GVWR)
- ***Motorcycles (MC)*** – All motorcycles (assumed to be gasoline-powered)

5.1.2 Vehicle Fleet Characterization

Based upon a review of recent DAF mobile source emission inventories, the vehicle categories that are most representative of the types of GOVs and POVs expected to be encountered on a typical DAF installation have been identified. The seven Air Force vehicle categories provide the most readily identifiable and discernible vehicle classes for vehicle mix identification and characterization. It is recognized that some vehicles encountered may not fit within the specific weight parameters of the categories chosen. In such instances, personnel conducting the AEI should use professional judgment to assign the vehicles to the listed category which most closely approximates the vehicle(s) in question. This approximation should be based on the fuel type and vehicle weight. Table 5-2 provides a breakdown of the fleet characterization for the typical POV and GOV vehicle mix at a DAF installation. **The vehicle mix provided in this table is to be used for estimating vehicle emissions unless specific vehicle mix data is available from a recent traffic study.**

5.1.3 Tactical Vehicles

Tactical vehicles are defined as any motor vehicle designed to military specifications to meet direct transportation support of combat, tactical or relief operations, or for training of personnel for such purposes. This also includes commercially designed motor vehicles modified to military specifications. Tactical vehicles are a subset of GOVs, and Table 5-3 provides vehicle mix percentages for tactical vehicles as well as non-tactical vehicles out of the total GOV vehicle mix. This supplemental information is provided if the need to calculate emissions specific to tactical or non-tactical vehicles arises.

Table 5-1. Air Force On-Road Vehicle Categories

CATEGORY		VEHICLE CLASS DESCRIPTION
Air Force	MOVES	
Gas/Diesel		
LDGV	LDGV	Light-Duty Gasoline Vehicles (Passenger Cars)
LDDV	LDDV	Light-Duty Diesel Vehicles (Passenger Cars)
LDGT	LDGT1	Light-Duty Gasoline Trucks 1 (0-6,000 lbs. GVWR, 0-3,750 lbs. LVW)
	LDGT2	Light-Duty Gasoline Trucks 2 (0-6,000 lbs. GVWR, 3,751-5,750 lbs. LVW)
	LDGT3	Light-Duty Gasoline Trucks 3 (6,001-8,500 lbs. GVWR, 0-5,750 lbs. ALVW)
	LDGT4	Light-Duty Gasoline Trucks 4 (6,001-8,500 lbs. GVWR, greater than 5,751 lbs. ALVW)
LDDT	LDDT1/2	Light-Duty Diesel Trucks 1 and 2 (0-6,000 lbs. GVWR)
	LDDT3/4	Light-Duty Diesel Trucks 3 and 4 (6,001-8,500 lbs. GVWR)
HDGV	HDGV2b	Class 2b Heavy-Duty Gasoline Vehicles (8,501-10,000 lbs. GVWR)
	HDGV3	Class 3 Heavy-Duty Gasoline Vehicles (10,001-14,000 lbs. GVWR)
	HDGV4	Class 4 Heavy-Duty Gasoline Vehicles (14,001-16,000 lbs. GVWR)
	HDGV5	Class 5 Heavy-Duty Gasoline Vehicles (16,001-19,500 lbs. GVWR)
	HDGV6	Class 6 Heavy-Duty Gasoline Vehicles (19,501-26,000 lbs. GVWR)
	HDGV7	Class 7 Heavy-Duty Gasoline Vehicles (26,001-33,000 lbs. GVWR)
	HDGV8a	Class 8a Heavy-Duty Gasoline Vehicles (33,001-60,000 lbs. GVWR)
	HDGV8b	Class 8b Heavy-Duty Gasoline Vehicles (>60,000 lbs. GVWR)
	HDGB	Gasoline Buses (School, Transit and Urban)
HDDV	HDDV2b	Class 2b Heavy-Duty Diesel Vehicles (8,501-10,000 lbs. GVWR)
	HDDV3	Class 3 Heavy-Duty Diesel Vehicles (10,001-14,000 lbs. GVWR)
	HDDV4	Class 4 Heavy-Duty Diesel Vehicles (14,001-16,000 lbs. GVWR)
	HDDV5	Class 5 Heavy-Duty Diesel Vehicles (16,001-19,500 lbs. GVWR)
	HDDV6	Class 6 Heavy-Duty Diesel Vehicles (19,501-26,000 lbs. GVWR)
	HDDV7	Class 7 Heavy-Duty Diesel Vehicles (26,001-33,000 lbs. GVWR)
	HDDV8a	Class 8a Heavy-Duty Diesel Vehicles (33,001-60,000 lbs. GVWR)

5.2 Emission Factors

Emissions from on-road vehicles include exhaust emissions, which occur both when the vehicle is in motion and while idling, as well as fugitive particulate emissions from road dust. The methodology for estimating emissions from each of these contributing sources is described in the following sections.

5.2.1 Vehicle Exhaust Emissions

The operation of on-road vehicles results in the generation of vehicle exhaust, which emits criteria pollutants, HAPs, and GHGs. Estimating emissions from vehicle exhaust is made more challenging because the number of pollutants emitted is different for a vehicle in normal operation versus when a vehicle is idling. The emissions total from vehicle exhaust is quantified by taking the sum of both the idling and normal operating exhaust emissions. **MOVES accounts for idling in proportion to normal driving, therefore calculation of idling emissions is not required for an AEI.** Particulate emissions estimation is made further complicated by the fact that particulate is emitted from vehicle exhaust from both idle and normal vehicle use, as well as from the suspension of road dust. The EFs for each contributing source are described in more detail below.

5.2.1.1 Vehicle Exhaust Emissions– Normal Vehicle Operation

EFs for the Air Force vehicle categories were obtained directly from MOVES4. The MOVES4 model was used to generate estimations of on-road vehicle emissions for each state (except California), the District of Columbia, and relevant US territories. This model requires various inputs such as population of personnel and VMT by vehicle type, age distribution and average speed distribution, ambient meteorological conditions, and elevation among other inputs. The “default” input database for MOVES4 was used for all calculations and derivations. The MOVES4 model was run for each state for calendar years 2024 through 2028 using the national estimates contained within the default database for all vehicle types listed in Table 5-1. The vehicle types selected for the run were all gasoline and diesel vehicles available in the MOVES database. The vehicle model years used for each run include the 30-year span from the calendar year of the run to 30 years prior. The output emission rates were averaged using an activity- (mileage) weighted average over all vehicle model years for each calendar year to estimate a representative emission factor for each pollutant for each vehicle type. The resultant EFs are provided in a gram/mile format and are presented in Table 5-19 through Table 5-23 for all states except California. The State of California uses the EMFAC2021 Model to calculate vehicle emissions. This model calculates emissions in a manner similar to MOVES in that it calculates emissions for all motor vehicles (across model years) in the state using data stored in a default database structured similarly to the MOVES database. EMFAC vehicle emissions data provided in this guide is on a county-basis for each county in California and is presented in Table 5-39

through Table 5-43. Vehicle-specific emission factors for California vehicle types are also included.

Additionally, there are composite EF tables included in this section. These values account for emission reductions resulting in the use of alternative fuels and are calculated using Air Force-specific vehicle mix data (refer to Section 5.2.1.3 for more information on alternative fuels). The composite EFs are provided in Table 5-9 through Table 5-18 and are presented chronologically by calendar year. Furthermore, since the calculation of composite EFs account for Air Force vehicle mix data, the tables are further subdivided into POV and GOV categories. The composite EFs for California were derived from EMFAC and are provided in Table 5-29 through Table 5-38. The model inputs and default values used to calculate EFs in MOVES and EMFAC are provided in Table 5-4 and Table 5-5, respectively.

Table 5-4. MOVES4 Model Inputs and Default Values

Model Input	Input Value
Scale	National

Pollutants and Processes	NO _x , SO _x , CO, ROG, PM ₁₀ , PM _{2.5} , CO ₂ , CH ₄
Activities	VMT, Population

There is no universally accepted set of EFs for installations located outside of the continental United States (OCONUS). Additionally, determining the vehicle mix or classifying vehicles may be more difficult in a foreign country. Calculating emissions for on-road vehicles at OCONUS facilities can be approximated by calculating the average of all state-specific composite EFs. The EFs for vehicle emissions at OCONUS installations are provided in Table 5-49 and Table 5-50 and are to be used with the same methodology as calculating on-road vehicle emissions within the United States.

5.2.1.2 Vehicle Exhaust Emissions – Idling

An idling vehicle wastes fuel, increases the cost of maintenance, and creates air pollution. Several states have adopted anti-idling restrictions with some including these restrictions in their SIPs. EFs for emissions from idling vehicles were developed and are provided in a gram/hour format. An idling vehicle is not in motion; therefore, emissions may not be calculated on miles driven, but rather on the time spent in idle. For this reason, the total amount of time that a vehicle spends in idle must be known or closely approximated. **Note that MOVES EFs already account for vehicle idling in proportion to normal driving. For this reason, the EFs provided in this chapter are presented for calculating theoretical emissions for NEPA, or for intersection modeling.** Idling EFs for each vehicle category are provided in Table 5-6.

Table 5-6. Idling Emission Factors for On-Road Vehicles

Vehicle Category	Emission Factors (g/hr)				
	CO	NO _x	VOC	PM ₁₀ ^a	PM _{2.5} ^b
LDGV (Passenger Cars)	71.225	3.515	2.683	---	---
LDGT (0-8,500 lb GVWR)	72.725	4.065	4.043	---	---
HDGV (>8,500 lb GVWR)	151.900	5.330	6.495	---	---

a. PM₁₀ is an average of HDDV particulate emissions.

b. PM_{2.5} value is assumed to be 92% of the PM₁₀ value per *Air Emissions Factor Guide to Air Force Mobile Sources*, December 2009.

“---” Indicates No Data Available

5.2.1.3 Alternative Fuel Emission Reduction Factors

Progressively stringent requirements resulting from the EPA, Presidential Executive Orders, DoD, and Air Force pollution prevention and energy conservation initiatives will result in an increasing number of GOVs and POVs powered by alternative fuels such as E85, CNG, or B20, and advanced hybrid electric vehicles (HEVs). Regardless of fuel type, all vehicles operating on alternative fuels are currently required to meet existing EPA emission standards established for gasoline and/or diesel-powered vehicles. However, some fuels offer potential emission reductions beyond those standards.

Relative to conventional gasoline, the higher-octane value and oxygen content of E85 fuel should lead to reduced vehicle emissions. The EPA’s Office of Transportation Air Quality (OTAQ) notes that while potential reductions will vary with engine design, E85 fuel should lead to reductions in VOCs, CO, PM, and NO_x relative to conventional gasoline (USEPA 2006a). The case with HAP emissions is not as clear since some data indicates a reduction in benzene and fewer total toxics, but an increase in ethanol and acetaldehyde emissions (USEPA 2006a). Adding to the complexity, some studies have shown that with the use of a catalytic converter, there is virtually no difference in exhaust emissions from on-road vehicles powered by gasoline. Due to these inconsistencies and the lack of clear data trends, **the application of E85 emission reduction factors is not recommended.**

CNG is recognized as one of the cleanest burning alternative fuels available and offers several advantages over gasoline (USDOE 2002). There is limited data for emissions reductions that CNG offers over conventional gasoline, especially since emissions will vary with engine design and performance. However, the EPA suggests that, relative to conventional gasoline-powered

vehicle applications, emissions from CNG-powered vehicles are estimated to be substantially lower for CO, PM, NO_x, and non-methane hydrocarbons.

There have been a few studies on the impacts of B20 fuel on vehicle emissions. In October 2002, the EPA issued a draft technical report on biodiesel emissions (USEPA 2002b). The EPA used the results from 39 studies to compare the difference in emissions between vehicles using B20 versus diesel fuel. Relative to low sulfur diesel (sulfur content of 500 ppm), B20 use resulted in notable reductions of NO_x, PM, HC, and CO emissions. Since the publication of the study, Ultra-Low Sulfur Diesel (ULSD) regulations that limit the sulfur content of on-highway diesel fuel to 15 ppm have been enacted and are in place across the country. Another study conducted under the auspices of the DoD Environmental Security Technology Certification Program (ESTCP) sought to measure the impact of B20 on emissions from engines used in on-road and portable power generation applications (DoD 2006). Whereas the EPA study used a B20/low sulfur diesel blend, the ESTCP study used a B20 biodiesel/ULSD blend to reflect the fact that conventional low sulfur diesel is no longer available for use in on-road vehicles. **The ESTCP study concluded that there were no statistically significant differences in criteria pollutant emissions between the B20 biodiesel blended with ULSD and ULSD by itself.** Likewise, no consistent trend was observed regarding HAP emissions.

Hybrid Electric Vehicles (HEVs) produce fewer criteria pollutant, HAP, and CO₂ emissions than comparable dedicated gasoline-powered vehicles. This is because HEVs utilize an electric motor in conjunction with a traditional, and often smaller, internal combustion engine. The electric motor decreases the frequency in which the combustion engine is used, which reduces fuel consumption and, therefore, emissions. Overall emissions will vary depending on several factors, including the vehicle's electrical storage capacity and how long it can operate in "electric-only" mode. Additional factors include how advanced the engine controls are, which emission standards the vehicles have been produced to meet, vehicle size, and model year. For these reasons, the emission profile of HEVs must be judged individually based on the miles traveled under each power mode, complicating attempts to estimate vehicle emission reductions. To estimate the potential emission reduction benefits from the use of HEVs, two sources were utilized: vehicle family application and emission certification data contained in the EPA OTAQ Certification and Fuel Economy Information System, and the California Air Resources Board (CARB) On-Road Vehicle and Engine Certification website. The assessment of representative certification data indicated NO_x, CO, HC (assumed to be equal to VOCs), and CO₂ were substantially reduced on average (U.S. Environmental Protection Agency, Office of Transportation Air Quality, Certification and Fuel Economy Information System).

Based upon this data, reduction factors for alternative fuels were calculated for on-road vehicles and are provided in Table 5-7. To estimate potential emission reductions from the use of these alternative fuels and advanced vehicle technologies, calculate vehicle emissions using the

MOVES4 gasoline or diesel fuel emission factors provided, and apply an appropriate percent impact based upon the values listed in the table.

Table 5-7. Alternative Fuel Emission Reduction Factors (FERFs)

Alternative Fuel (Original fuel type)	Vehicle Category	Fuel Reduction Emission Factor (%)

5.2.2 Fugitive Particulate Matter (PM) Emissions

Though roads are themselves stationary, the generation of airborne road dust is the result of the turbulent wake created by on-road vehicles, which are mobile sources. Therefore, road dust emissions are provided in this section. **Note that this section does not describe emissions from asphalt paving since those operations are considered transitory and are addressed in the *Air Emissions Guide for Air Force Transitory Sources*.** Since fugitive PM emissions are the result of road dust suspended as the vehicle moves across a road surface, the extent of the emitted PM is dependent on whether the road surface is paved or unpaved. These surfaces are subjected to strong air currents from the turbulent wake that follows behind a vehicle as it passes. The currents disturb the loose material pulverized under the weight of the vehicle and PM is cast into the air. PM emissions will fluctuate for several reasons, including construction activities in the area, road degradation due to vehicular traffic, and the application of granular material for snow and ice control. Typically, the most important factors regarding road PM emissions are the number and weight of the vehicles that travel the road, and the VMT. Paved and unpaved road EFs are already derived and may be found in Table 5-8.

Table 5-8. Fugitive PM Emission Factors

	POV		GOV	
	PM ₁₀ (g/mi)	PM _{2.5} (g/mi)	PM ₁₀ (g/mi)	PM _{2.5} (g/mi)
Paved Road	0.058	0.014	0.069	0.017
Unpaved Road	466.206	46.621	505.981	50.598

The EFs for suspension of loose material on paved and unpaved road surfaces due to vehicle travel were derived from the following empirical equations from AP-42 Chapter 13.2.1 (Jan 2011) and AP-42 Chapter 13.2.2 (Nov 2006):

$$EF(Pol)_P = k(Pol) \times (sL)^{0.91} \times W^{1.02} \quad \text{AP-42 Chapter 13.2.1.3}$$

Where,

- EF(Pol)_p** = Particulate emission factor for **paved** roads (g/mi)
- k(Pol)** = Particle size multiplier (g/mi). **PM_{2.5} = 0.25 and PM₁₀ = 1.00**
- sL** = Road surface silt loading (g/m²). **AP-42 Chapter 13.2.1 recommends a default value of 0.015 for limited access roadways (such as Air Force roads)**
- W** = Average weight of the vehicles traveling the road (tons). **POVs = 2.581 and GOVs = 3.096**

$$EF(Pol)_U = k(Pol) \times \left(\frac{s}{12}\right)^a \times \left(\frac{W}{3}\right)^b \times 453.6 \quad \text{AP-42 Chapter 13.2.2.2}$$

Where,

- EF(Pol)_U** = Particulate emission factor for **unpaved** roads (g/mi)
- k(Pol)** = Particle size multiplier (lb/mi). **PM_{2.5} = 0.15 and PM₁₀ = 1.5**
- s** = Surface material silt content (%). **AP-42 Chapter 13.2.2 value for construction site road value of 8.5**
- a, b** = Empirical constants for industrial roads from AP-42 Table 13.2.2-2. **a=0.9 and b=0.45**
- 453.6** = Factor converting lbs to grams (g/lb)

***Note:** The equation above calls for the average weight of all vehicles traveling the road and is **not** intended to be used to calculate a separate EF for each vehicle weight class. Rather, one EF should be calculated to represent the “fleet” average weight of all vehicles.

5.2.2.1 Corrected Emission Factors Accounting for Precipitation

Average fugitive PM emissions are inversely proportional to the frequency of measurable precipitation (>0.01 inch). The total fugitive PM emissions are calculated using the appropriate EF listed above, the total vehicle miles traveled, and a precipitation correction factor. When accounting for precipitation, the fugitive PM EFs must be corrected. The corrected EFs for both paved ($EF(Pol)_{CP}$) and unpaved ($EF(Pol)_{CU}$) roads are calculated as follows:

$$EF(Pol)_{CP} = EF(Pol)_P \times \left(1 - \frac{P}{4N}\right)$$

Equation 5-1

$$EF(Pol)_{CU} = EF(Pol)_U \times \left(1 - \frac{P}{N}\right)$$

Equation 5-2

Where,

- $EF(Pol)_{CP/CU}$ = Corrected emission factor for paved or unpaved roads (g/mi)
- P = Number of days in the inventory period in which at least 0.01 inches of precipitation was measured (days). See Figure 5-1 to determine this value based on the installation's geographic location.
- N = Number of days in the inventory period (days). 1 year = 365 days

***Note** – The paved road precipitation factor differs from the unpaved precipitation factor since it incorporates a factor of 4 in the denominator to account for the fact that paved roads dry more quickly than unpaved roads.

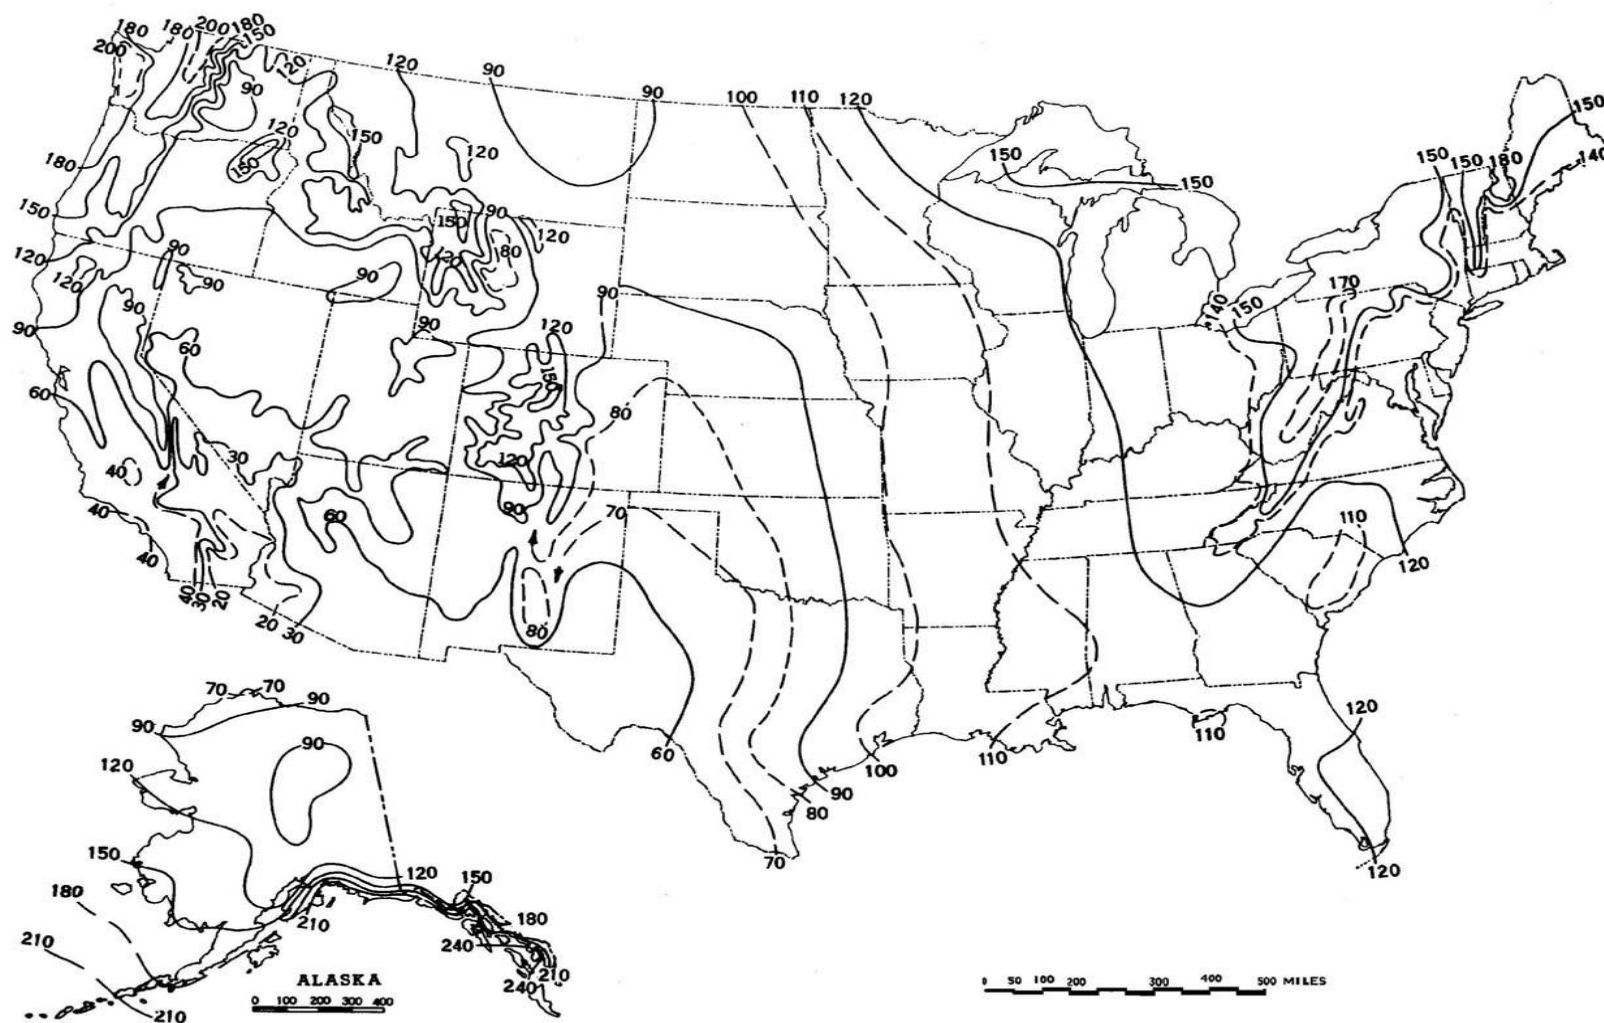

Figure 5-1. Mean Number of Days in the Year with Precipitation of 0.01 Inches or More

5.3 Emission Calculations

The total emissions from the operation of on-road vehicles are the sum of the emissions from the vehicle exhaust and fugitive PM from road dust. There are three accepted methods for estimating vehicle emissions. The first, which is the simplest and preferred method, uses Air Force/State/Territory composite EFs. The second method uses POV and GOV fleet mix from recent traffic studies. The third and final method uses the typical DAF POV and GOV fleet mix from Table 5-2. **No matter which method is used for estimation, POV and GOV emissions are calculated independently.**

5.3.1 Vehicle Exhaust Emissions – Typical Vehicle Operation

Calculating emissions from vehicle exhaust is dependent on the VMT and appropriate EF. Vehicle exhaust emissions are directly dependent on the vehicle mix at the installation. There are two circumstances that determine the method for calculating vehicle exhaust emissions – when the specific vehicle mix is known, or when it is unknown. If the vehicle mix is known, that data may be used for emissions calculations. If the vehicle mix is unknown, the mix from Table 5-2 may be assumed. Calculating these emissions is discussed below.

5.3.1.1 Method 1: Using Air Force/State/Territory Composite Emission Factors (Preferred Method)

This is the preferred method for emissions estimates because it is the simplest method to use. The EFs used for this method are selected based on the emission inventory year and the state/territory in which the installation is located. The Air Force/State/Territory composite EFs ($EF(Pol)_{Comp}$) were derived using the assumed vehicle mix as provided in Table 5-2 and Table 5-19 through Table 5-23 for most states. For the State of California, the composite values are provided in Table 5-29 through Table 5-38. Use Table 5-49 and Table 5-50 for OCONUS installations. Note that the tables are separated into POV and GOV since the EFs account for the vehicle mix which differs between these two classifications. **Also note that these EFs have already been adjusted to reflect the reduction in emissions due to vehicles that operate on alternative fuels.** Therefore, no additional calculation is needed to account for the reduction in emissions from the use of alternative fuels. Emissions calculation using the adjusted EFs is estimated as follows:

$$E(Pol)_{Total} = VMT_{Total} \times EF(Pol)_{Comp} \times 0.002205$$

Equation 5-3

Where,

- E(Pol)_{Total}** = Total annual emissions of specific pollutant from vehicle exhaust (lb/yr)
- VMT_{Total}** = Total annual vehicle miles traveled for all POV or GOV (mi/yr). This should be available for GOVs through records or estimated for GOVs and POVs using Equation 5-4 and Equation 5-5 respectively. **Note that this includes both paved and unpaved roads, as applicable.**
- EF(Pol)_{Comp}** = Air Force/State/Territory composite EF for specific pollutant (g/mi) from Table 5-9 through Table 5-18 and for California, Table 5-29 through Table 5-38.
- 0.002205** = Factor for converting grams to pound (lb/g)

Emissions from GOVs and POVs are calculated using the general formula provided in Equation 5-3. **These steps must be completed independently for each pollutant of concern. Note GOVs and POVs should not be combined, and their emissions must be calculated independently.** Due to the complexity of calculating on-road vehicle emissions, the following steps are recommended for use as a guideline for data collection and emissions calculations:

Step 1 – Gather fleet data. The first step is to determine the number of POVs or GOVs (N) operating on base. Also, the total vehicle miles traveled (VMT_{Total}) or average vehicle miles traveled (AVM) for GOVs should be recorded. This data can often be provided or estimated by the Security Forces Squadron (from the Pass & Registration section) and/or the Military Personnel Flight (MPF). For POVs, VMT_{Total} is calculated using Equation 5-5 while Equation 5-4 may be used to calculate VMT_{Total} for GOVs only if necessary.

Vehicle Miles Traveled for GOVs:

The total vehicle miles traveled (VMT_{Total}) for GOVs is the sum of all the miles driven using GOVs during the inventory period. These values should be available through records kept by the base transportation organization or directly from the organizations that operate and/or maintain the vehicles. Alternatively, VMT_{Total} may be estimated if it is assumed that each vehicle category traveled the same distance per year, as shown:

$$VMT_{Total} = AVM \times N$$

Equation 5-4

Where,

- VMT_{Total}** = The total vehicle miles traveled for all GOV vehicles (mi/yr)
- AVM** = The annual average miles traveled per vehicle (mi/yr)
- N** = The number of vehicles – GOV in this case – at the installation

Vehicle Miles Traveled for POVs:

For POVs, the suggested method for estimating VMT_{Total} is to assume that each POV in operation on an installation travels twice the distance from the main gate to the population centroid of the installation. Not every person will operate their vehicle every day of the year so it is assumed that the majority of POVs will be driven during the workweek. Additionally, a statistical analysis of available Employee-Certification and Reporting System (ECARS) data revealed that typically only 70% of the installation population operates their vehicles on the installation during the week. Using this information, the VMT_{Total} for POVs is estimated as follows:

$$VMT_{Total} = D \times 520 \times 0.7 \times P$$

Equation 5-5

Where,

- D** = One-way distance from the main gate to the population centroid of the installation (miles/trip)
- 520** = Factor converting the number of miles per trip to miles per year (trips/year)
- 0.7** = Fraction of the installation population that operates their vehicle during the week
- P** = Installation population

In Equation 5-5, the 520-multiplying factor was derived as follows:

$$2 \frac{\text{trips}}{\text{days}} \times 5 \frac{\text{days}}{\text{weeks}} \times 52 \frac{\text{weeks}}{\text{yr}} = 520 \frac{\text{trips}}{\text{yr}}$$

Step 2 – Select emission factors. These are provided in **Table 5-19** through **Table 5-28** for all states other than California, **Table 5-39** through **Table 5-48** for California, or **Table 5-49** and **Table 5-50** for OCONUS installations.

Step 3 – Calculate emissions. Emissions of each pollutant (and vehicle classification) are calculated *independently* using Equation 5-3.

5.3.1.2 Method 2: Using Specific Vehicle Mix Data

This method is more intensive than the preferred method given above. However, it may be desirable if a recent traffic study conflicts with the typical vehicle mix provided, or if emissions from each vehicle category are required. The EFs used for this method are selected based on the emission inventory year, the state in which the installation is located, and the vehicle category (LDGV, LDDV, etc.). Additionally, they can be found in Table 5-19 through Table 5-28 (for states other than California) and Table 5-39 through Table 5-48 for California. To account for the reduction in emissions due to the use of alternative fuels, the appropriate emissions reduction

factor, as given in Table 5-7, is employed. Emissions are estimated using the VMT for each vehicle category and summed as follows:

$$E(Pol)_{Total} = \sum_{i=1}^n \left\{ VMT_i \times EF(Pol)_i \times \left[1 - \frac{FERF(Pol)}{100} \right] \times 0.002205 \right\}$$

Equation 5-6

Where,

E(Pol)_{Total} = Total annual emissions of specific pollutant from vehicle exhaust (lb/yr)

VMT_i = Total annual vehicle miles traveled for each vehicle class (mi/yr).

This should be available for GOVs through records and estimated for POVs using Equation 5-5. Note that this includes both paved and unpaved roads, if applicable.

EF(Pol)_i = Air Force/State/Territory emission factor for specific pollutant (g/mi)

FERF(Pol) = Pollutant-specific fuel emission reduction factor, as applicable (%). This is provided in Table 5-7.

100 = Factor converting percent to fraction

0.002205 = Factor converting grams to pounds (lb/g)

To accurately account for the reduction of emissions using alternative fuels, the VMT_i for each hybrid and CNG vehicle should be known and treated as a separate vehicle category. If the annual VMT for each vehicle category is not known, the following equation may be used to approximate VMT for each specific vehicle category (VMT_i):

$$VMT_i = AVM_i \times n_i = AVM_i \times N \times \frac{MIX_i}{100}$$

Equation 5-7

Where,

AVM_i = Average annual vehicle miles traveled by each vehicle category (mi/yr)

n_i = Number of vehicles in a specific vehicle category

N = Total number of vehicles (POV or GOV)

MIX_i = Vehicle mix for a specific vehicle category (%)

To quantify the emissions from on-road vehicles using this method, the following process is recommended:

Step 1 – Gather fleet data. Data required to calculate vehicle emissions typically includes vehicle category, model year, and vehicle miles traveled. (VMT_i) during the year in question.

- a. **GOV Fleet Mix Data:** If a GOV is driven both on and off base during the inventory year, an estimate must be made to apportion the number of miles driven between off and on installation miles. The best way to collect GOV information is to provide blank forms for each vehicle category to the installation organization(s) responsible for managing GOVs.
- b. **POV Fleet Mix Data:** Prior to conducting an AEI that includes POVs, it is recommended that the individual responsible for preparing the mobile source emission inventory contacts the Base Development and/or Community Planning section of the Civil Engineering Squadron. This is to determine if a traffic survey has been conducted recently at the installation, which may contain information that will be useful in calculating POV emissions.

If a recent traffic survey is not available, and resources do not allow for a new traffic survey to be conducted, data provided by the Security Forces Squadron (from the Pass & Registration section) and/or the Military Personnel Flight (MPF) can be used to estimate POV fleet data. Types of data that can usually be obtained from the Security Forces Squadron and/or MPF include:

- 1) The estimated average number of registered POVs at the installation during the applicable inventory year.
- 2) The estimated percentage of registered vehicles that fall under the seven vehicle categories.
- 3) The estimated distance (in miles) of the average POV trip on the installation during a typical weekday and weekend day.
- 4) The estimated distance (in miles) of non-registered vehicles that travel on the installation during a typical weekday and weekend day.

An alternative approach to obtaining vehicle registration information may be available at some installations as some installations may be able to provide a listing of the vehicles contained in their databases.

Step 2 – Group vehicle categories. Upon gathering fleet data, group together all vehicles based on the DAF vehicle categories identified in Table 5-1. Record the number of vehicles (n_i) and total annual miles traveled (VMT_i) for each vehicle category.

- a. If VMT_i is unknown, it can be estimated using Equation 5-7.

- b. If there is insufficient fleet data to provide the number of vehicles (n_i) for each vehicle category despite the total number of vehicles and associated relative vehicle mix (MIX_i) for each specific category being known, the equation below can be used to estimate n_i :

$$n_i = N \times \frac{MIX_i}{100}$$

Step 3 – Select emission factors. The appropriate EFs are selected based on the vehicle category, the calendar year for which emissions calculations are being performed, and the installation's geographic location. Vehicle exhaust EFs are selected from Table 5-19 through Table 5-28 for states other than California, Table 5-39 through Table 5-48 for California emissions calculations, and for OCONUS, Table 5-49 and Table 5-50.

Step 4 – Calculate emissions. For vehicle exhaust emissions, calculate the emissions for each individual vehicle category and sum these values for the total vehicle emissions for that pollutant. Pollutant emissions for each vehicle category are calculated using Equation 5-6.

5.3.1.3 Method 3: Using DAF Typical Vehicle Mix Data

Another method for calculating on-road vehicle emissions is to calculate the emissions from each vehicle category using the typical DAF vehicle mix. This method is like that of calculating emissions using specific vehicle mix data. The EFs used for this method are selected based on three metrics: 1) the emission inventory year, 2) the state in which the installation is located, and 3) the vehicle category. Emissions are estimated via this method using a modified version of Equation 5-3 by substituting the correct EF as shown:

$$E(Pol)_{Total} = VMT_{Total} \times EF(Pol)_{Total} \times 0.002205$$

Equation 5-8

Where,

$EF(Pol)_{Total}$ = Total adjusted on-road vehicle exhaust emissions (lb/yr).

The total adjusted on-road vehicle EF considers any reduction in emissions due to alternative fuel use. This is calculated as follows:

$$EF(Pol)_{Total} = \sum_{i=1}^n \left\{ \left(\frac{MIX_i}{100} \right) \times EF(Pol)_i \times \left[1 - \frac{FERF(Pol)}{100} \right] \right\}$$

Equation 5-9

The total vehicle miles traveled (VMT_{Total}) is the sum of the average miles traveled for all vehicle categories as shown:

$$VMT_{Total} = \sum_{i=1}^n \left(AVM_i \times N \times \frac{MIX_i}{100} \right)$$

Equation 5-10

Emissions from vehicles are calculated by applying the equations in Method 2 using the typical POV or GOV vehicle mix data from Table 5-2. **These steps must be completed separately for each pollutant of concern. GOVs and POVs should not be combined, and their emissions should be calculated independently of each other.** Due to the complexity of calculating on-road vehicle emissions, the following steps are recommended for use as a guideline for data collection and emissions calculations:

Step 1 – Gather fleet data. In this case, fleet data or a traffic survey for the base is not available. Therefore, obtain the total number (N) of vehicles (POV or GOV) driving on base and the overall average annual vehicle miles traveled (AVM) for all vehicle categories. The data can often be provided or estimated by the Security Forces Squadron (from the Pass & Registration section) and/or the Military Personnel Flight (MPF) can be used to estimate POV fleet data. Types of data that can usually be obtained from the Security Forces Squadron and/or MPF include: 1) the estimated average number of registered POVs and/or GOVs at the installation during the applicable inventory year; 2) the estimated distance (in miles) of the average POV travels on the installation during a typical weekday and weekend day; and 3) the estimated number of non-registered vehicles that travel on the installation during a typical weekday and weekend day.

An alternative approach to obtaining vehicle registration information may be available at some installations. Data such as listings of vehicles held in databases (preferably in hardcopy format) as well as the number of registered vehicles are examples of alternative data options that may be available at specific installations.

Step 2 – Group vehicle categories. Upon gathering fleet data on the total number (N) of vehicles (POV or GOV) driving on base and overall average AVM, obtain and record the typical vehicle mix values (MIX_i) from Table 5-2 for each vehicle category. Then, assuming all vehicle categories traveled the same distance per year, calculate the total annual vehicle miles traveled (VMT_{Total}) for all vehicle categories combined using Equation 5-4.

Step 3 – Select emission factors. Selection of the appropriate EF is based on the vehicle category, the calendar year being calculated for, the installation's location (state), and the installation's altitude. The EFs are then selected from Table 5-19 through Table 5-28 for all states except California, Table 5-39 through Table 5-48 for California, or Table 5-49 and Table 5-50 for OCONUS installations.

Once the appropriate pollutant specific EFs for each vehicle have been obtained, calculate the total composite EF using Equation 5-9.

Step 4 – Calculate emissions. The total pollutant emissions, on a per vehicle category-basis, for on-road emissions are calculated using Equation 5-8.

5.3.2 Vehicle Exhaust Emissions – Idling

Calculating idling emissions uses slightly modified versions of equations used for calculating on-road emissions caused by normal vehicle operation as discussed in the previous sections. The primary difference is that the EFs for idling vehicles are presented as grams/hr, meaning the time spent in idle mode must be known (or estimated). Idling emissions from typical on-road vehicle operation have also been addressed in the previous section. Estimating the emissions from vehicle idling is performed under two circumstances: 1) where the vehicle mix is known (e.g., from a recent traffic study) and 2) where the typical DAF vehicle mix is used. **This section describes the calculation of *theoretical* emissions from idling vehicles for NEPA and intersection modeling, not for a mobile AEI.**

5.3.2.1 Method 1: Using Specific Vehicle Mix Data

If necessary, emissions may be calculated using a specific vehicle mix different from the one provided in Table 5-2. This method may be desirable if a recent traffic study conflicts with the typical vehicle mix provided. The EFs used for this method are selected based on the vehicle category. These EFs are provided in Table 5-6. Idling emissions are estimated as follows:

$$E(Pol)_{Total} = \sum_{i=1}^n \left\{ VIT_i \times EF(Pol)_i \times \left[1 - \frac{FERF(Pol)}{100} \right] \times 0.002205 \right\}$$

Equation 5-11

Where,

- E(Pol)_{Total}** = Total theoretical emissions of specific pollutant from idling (lb/yr)
- VIT_i** = Annual vehicle idling time (hr/yr)
- EF(Pol)_i** = Idling emission factor for specific pollutant (g/hr) from Table 5-6.

The vehicle idling time is the most difficult parameter to determine. Depending on the proposed action, idling times of varying lengths may be recommended for each vehicle *category* and/or *classification*. The idling time for each vehicle category may be estimated using an average idling time as shown:

$$VIT_i = AVIT_i \times n_i = AVIT_i \times N \times \frac{MIX_i}{100}$$

Equation 5-12

Where,

AVIT_i = Average annual vehicle idling time (hr/yr)

5.3.2.2 Method 2: Using Air Force Typical Vehicle Mix Data

If the specific vehicle mix data is not available from a recent traffic study, the typical vehicle mix from Table 5-2 can be assumed. The EFs used for this method are selected based on the Air Force vehicle category. These EFs can be found in Table 5-6. Theoretical emissions from vehicle idling using this method are calculated as follows:

$$E(Pol)_{Total} = VIT_{Total} \times EF(Pol)_{Total} \times 0.002205 \quad \text{Equation 5-13}$$

Where,

VIT_{Total} = Total annual vehicle idling time for all POVs or GOVs (hr/yr)
EF(Pol)_{Total} = Total adjusted idling emission factor (g/hr). Calculated using Equation 5-14 below.

The total adjusted idling EF considers any reduction in emissions due to alternative fuel use and is calculated as follows:

$$EF(Pol)_{Total} = \sum_{i=1}^n \left\{ EF(Pol)_i \times \frac{MIX_i}{100} \times \left[1 - \frac{FERF(Pol)}{100} \right] \right\} \quad \text{Equation 5-14}$$

The total vehicle idling time (VIT_{Total}) is the sum of the average idling time for all vehicles categories as shown below:

$$VIT_{Total} = \sum_{i=1}^n \left(AVIT_i \times N \times \frac{MIX_i}{100} \right) \quad \text{Equation 5-15}$$

Equation 5-15 may be simplified if it is assumed that each vehicle category will idle for the same amount of time per year. This simplification reduces Equation 5-15 to the equation that follows:

$$VIT_{Total} = AVIT \times N \quad \text{Equation 5-16}$$

In the absence of average vehicle idling time (AVIT) data, contact Base CE for assistance in estimating this value.

5.3.3 Fugitive PM Emissions

Particulate emissions are generated from vehicle exhaust and are described in the previous sections. Fugitive particulate emissions, however, are generated from the operation of on-road vehicles across paved or unpaved road surfaces. The amount of particulate generated is a function of the road surface (paved or unpaved) and the total vehicle miles traveled (VMT_{Total}). The EFs are selected from Table 5-8 based on the road surface type (paved or unpaved) and vehicle classification (POV or GOV). The selected EFs must be corrected based on the number of days in the year with precipitation greater than or equal to 0.01 inches using the appropriate equation (either Equation 5-1 or Equation 5-2) and the type of road surface. Using the corrected EF for paved or unpaved roads ($EF(Pol)_{CP}$ or $EF(Pol)_{CU}$ respectively), fugitive PM emissions are calculated as follows:

$$E(Pol)_{Total} = VMT_{Total} \times \left\{ \left[\frac{\%VMT_P}{100} \times EF(Pol)_{CP} \right] + \left[\frac{\%VMT_U}{100} \times EF(Pol)_{CU} \right] \right\} \times 0.002205$$

Equation 5-17

Where,

$E(Pol)_{Total}$ = Total annual emission of fugitive PM from on-road vehicles (lb/yr)

$\%VMT_P$ = Percent of total miles driven on paved roads (%)

$\%VMT_U$ = Percent of total miles driven on unpaved roads (%)

5.3.4 VOC Speciation

On-road vehicles have the potential to produce a significant amount of air pollutants released into the atmosphere. The amount of pollution is a function of the number of on-road vehicles, the average number of miles driven, the time of year, the content of the fuel used, and even the average idling time. The large number of variables impacting air emissions from on-road vehicles increases the complexity of quantifying their emissions. However, measurements are continually being taken to develop more accurate air emissions estimates. Individual VOCs may be estimated using the weight fractions of each chemical to the total emitted VOC.

The weight fractions provided in this document were determined using test data from a variety of sources, including the EPA's *SPECIATE* database. The emission profiles used to determine the VOC weight percent are assumed to be representative of the vehicle category's emissions. However, this information should only be used when no alternative emission profiles are available. The average weight percent of individual pollutants were calculated using the following equations:

$$P_{Pol} = \frac{A_{Pol}}{AVOC_{Total}}$$

Equation 5-18

Where,

- P_{Pol} = Weight percent of a given pollutant (%)
 A_{Pol} = Individual pollutant emission factor (mg/mi)
 $AVOC_{Total}$ = Total VOC emission factor (mg/mi)

Speciated VOCs are calculated by taking the product of the total VOCs and the weighted percentage of the individual VOC as follows:

$$E_{Pol} = E_{VOC} \times \frac{P_{Pol}}{100}$$

Equation 5-19

Where,

- E_{Pol} = Emission of speciated VOC (lb/yr)
 100 = Factor for converting percent to a fraction (%)
 E_{VOC} = Emissions of total VOC (lb/yr)

The percentages of each VOC to total VOC are provided in Table 5-51. Note that the light-duty gas vehicles, light-duty gas trucks, and heavy-duty gas vehicles (LDGV, LDGT, and HDGV) are not further subdivided into hybrid and CNG-fueled vehicles. To calculate emissions specific to these vehicles, apply the vehicle mix (using the default values if no onsite data is available).

5.4 Information Resources

Information required for calculating emissions from GOVs can usually be obtained from the installation transportation organization as it typically maintains records on most, if not all, GOVs assigned to the installation. At some installations, it may also be necessary to obtain information directly from the organizations that use and/or maintain the vehicles. For example, the Fire Department may need to be contacted to obtain information specific to fire trucks and rescue vehicles.

In some cases, it may be necessary to obtain and review data contained in the installation's vehicle maintenance index file (VMIF), on-line vehicle interactive management system (OLVIMS) report, or equivalent vehicle information management system to verify vehicle class/type as some installations do not use the same classification system used by the EPA.

Some facilities may have a cross-reference tool with management codes that will assist in interpreting how vehicle usage is being tracked (e.g., miles, hours, and kilometers).

Most information required to calculate POV emissions may be obtained from the Security Forces Squadron. The Pass & Registration section of the base Security Forces Squadron usually maintains computer records on all POVs registered at the installation. Some installations perform vehicle registration at MPF. The office that handles vehicle registrations (Pass & Registration or MPF) is also in a good position to survey personnel on their vehicle usage. Since the Security Forces Squadron is responsible for staffing the installation gates, they are usually the best source of information on non-registered vehicles.

If the POV information needed to calculate vehicle emissions cannot be obtained from the Security Forces Squadron, it might be necessary to survey a representative number of installation personnel to obtain the required information. It is also highly recommended that personnel conducting the AEI check with the Base Development and/or Community Planning sections of the Civil Engineering Squadron to determine whether any recent traffic surveys have been conducted.

For purposes of estimating the length of typical on-installation POV trips, consider the trip length in terms of the mileage from the main gate to a common on-installation destination and back. For instance, if most POVs are believed to be traveling to the Base Exchange, the Commissary, or the Medical Clinic, estimate the distance from the main gate to those locations. In such instances, it may be assumed that a median round-trip distance of 3-4 miles is appropriate for use. However, it may also be necessary to estimate vehicle travel distances for individuals who travel on and off the installation more than once per day, such as personnel who leave during lunchtime. **In the absence of installation-specific survey data, it can be conservatively assumed that 5% of installation personnel will travel off-installation during lunchtime.** Since this is a second trip through the gate, you should assume the daily on-installation mileage is doubled for those individuals. If installation organizations are unable to provide required data, it may be possible to obtain trip length and driver behavior data that can be extrapolated to on-installation conditions from the local metropolitan planning office (MPO).

5.5 Example Problems

5.5.1 Problem 1 – Calculating POV and GOV Emissions Using Method 1

A DAF base in performing an air emissions inventory for calendar year (CY) 2024 CO emissions for their POVs and GOVs operated by the facility during the year. Data indicates that there is a total of 422 POVs and 38 GOVs and all vehicles traveled an average of 4,563 miles each. Calculate CO emissions for CY2024 if the base is in Alabama.

Step 1 – Gather fleet data. The data required to calculate emissions is provided in the problem statement. This information includes the number of POVs ($N_{POV} = 422$), the number of GOVs ($N_{GOV} = 38$), and the average miles traveled for each vehicle ($AVM = 4,563 \text{ mi/yr}$).

Next, calculate total vehicle miles traveled (VMT_{Total}). Using the number of POVs and GOVs, the average vehicle miles traveled (AVM), and Equation 5-4, the VMT_{Total} is calculated as follows:

$$VMT_{Total} = AVM \times N$$

For POVs

$$VMT_{Total-POV} = 4,563 \frac{\text{mi}}{\text{yr}} \times 422 = 1,925,586 \frac{\text{mi}}{\text{yr}}$$

For GOVs:

$$VMT_{Total-GOV} = 4,563 \frac{\text{mi}}{\text{yr}} \times 38 = 173,394 \frac{\text{mi}}{\text{yr}}$$

Step 2 – Select emission factors. According to Table 5-9, for CY2024 in Alabama, the CO EF ($EF(CO)_{Alabama}$) for POVs is **4.506 g/mi**. Similarly, the CO EF ($EF(CO)_{Alabama}$) for GOVs is **4.153 g/mi**.

Step 3 – Calculate emissions. Emissions are calculated using the adjusted EFs from Step 2, the VMT_{Total} calculated from Step 1, and Equation 5-3 as shown below:

$$E(Pol)_{Total} = VMT_{Total} \times EF(Pol)_{Total} \times 0.002205$$

For POVs:

$$E(CO)_{Total} = 1,925,586 \frac{\text{mi}}{\text{yr}} \times 4.506 \frac{\text{g}}{\text{mi}} \times 0.002205 \frac{\text{lb}}{\text{g}}$$

$$\boxed{E(CO)_{Total} = 19,132.10 \frac{\text{lb}}{\text{yr}}}$$

For GOVs:

$$E(CO)_{Total} = 173,394 \frac{\text{mi}}{\text{yr}} \times 4.153 \frac{\text{g}}{\text{mi}} \times 0.002205 \frac{\text{lb}}{\text{g}}$$

$$\boxed{E(CO)_{Total} = 1,587.83 \frac{\text{lb}}{\text{yr}}}$$

5.5.2 Problem 2 – Calculating GOV Emissions Using Method 2

A DAF base is performing an inventory for CY2024 CO emissions for their 15 GOVs operated by the facility during the year. The Air Force Base is in Alabama.

Step 1 – Gather fleet data and Step 2 – Group vehicle categories. Since the data was available from the Environmental manager, steps 1 and 2 are combined.

Installation Name: Anytown AFB			Inventory Year: 2024

Vehicle #12	Fire Truck	Bldg. 45-2	2002	5,300
		Average	2002	5,300
		Total		5,300

Step 3 – Select emission factors. For vehicles in CY2024 in Alabama, the CO EFs for each vehicle category are given in Table 5-19. The EFs are provided in the table below.

Vehicle Category	CO Emission Factor (g/mi)
LDGV	4.527
LDGT	4.089
HDGV	11.927
LDDV	5.385
LDDT	5.362
HDDV	1.592
MC	12.896

Step 4 – Calculate emissions. No information was provided regarding whether any of the vehicles operated on alternative fuel. Using the vehicle miles traveled for each vehicle category (VMT_i) from the fleet data, the EFs recorded in Step 3, and Equation 5-6, the emissions are first calculated for each vehicle category as follows:

$$E(Pol)_{Total} = \sum_{i=1}^7 \left\{ VMT_i \times EF(Pol)_i \times \left[1 - \frac{FERF(Pol)}{100} \right] \times 0.002205 \right\}$$

$$E(CO)_{LDGV} = 34,888 \frac{mi}{yr} \times 4.527 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 323.77 \frac{lb}{yr}$$

$$E(CO)_{LDGT} = 19,500 \frac{mi}{yr} \times 4.089 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 175.82 \frac{lb}{yr}$$

$$E(CO)_{HDGV} = 4,450 \frac{mi}{yr} \times 11.927 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 108.80 \frac{lb}{yr}$$

$$E(CO)_{LDDV} = 0 \frac{mi}{yr} \times 5.38 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 0.0 \frac{lb}{yr}$$

$$E(CO)_{LDDT} = 4,300 \frac{mi}{yr} \times 5.362 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 50.84 \frac{lb}{yr}$$

$$E(CO)_{HDDV} = 5,300 \frac{mi}{yr} \times 1.592 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 18.60 \frac{lb}{yr}$$

$$E(CO)_{MC} = 0 \frac{mi}{yr} \times 12.896 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 0.0 \frac{lb}{yr}$$

Finally, the total CO emission are calculated by summing the contributing CO emission from each vehicle category.

$$E(Pol)_{Total} = \sum_{i=1}^7 E(Pol)_i$$

$$E(CO)_{TOTAL} = (323.77 + 175.82 + 108.80 + 0 + 50.84 + 18.60 + 0) \frac{lb}{yr}$$

$$E(CO)_{TOTAL} = 677.83 \frac{lb}{yr}$$

5.5.3 Problem 3 – Calculate POV Emissions Using Method 2

A DAF Base (located in Alabama) is conducting an emissions inventory to quantify CY2024 emissions attributable to the operation of POVs. Using the information provided by the Security Forces Squadron, the following data was used to calculate the CY2024 emissions of CO from the operation of POVs.

Step 1 – Gather fleet data. Fleet data information is provided in the figure following Step 2.

Step 2 – Group vehicle categories. The first step in grouping the vehicle categories is to calculate the estimated total number of vehicles (N) driving on base. Using the data provided in the form referenced in Step 1, the total number of POVs is estimated as follows:

$$N = Registered + Unregistered$$

$$N = 1,675 + 125 = 1,800 \text{ vehicles}$$

Installation Name: Anytown AFB		Inventory Year: 2024
Responsible Organization (Name and Office Symbol): 58 CES/CD		
POC (Name, Phone #, and email): SSgt John Jones, DSN 234-5678		
Question	Response	
Can you provide the listing of all registered vehicles on base? (Y/N)? If so, be sure to include all specific information (make/model year, etc.) about the vehicles.	N	
What is the estimated average number of <u>registered</u> POVs at the installation during the inventory period?	1,675	
What is the estimated percentage of <u>registered</u> vehicles which travel on the installation during a typical weekday (Monday-Friday)?	75	
What is the estimated percentage of <u>registered</u> vehicles which travel on the installation during a typical weekend day (Saturday and Sunday)?	50	
What is the estimated distance the average POV travels on base during a typical weekday?	6 mi/day	
What is the estimated distance the average POV travels on base during a typical weekend day?	4 mi/day	
What is the estimated number of <u>non-registered</u> POVs which travel on base during a typical weekday?	125	
What is the estimated average model year of all POVs driven on base during the inventory year? (NOTE: This is not required if the average model years are listed below for each vehicle category)		
Using registration information, provide an estimate of the percentage of <u>registered</u> POVs which fall under each of the 7 vehicle categories listed below.		
Vehicle Category	Category Description	Estimated % of Registered Vehicles
LDGV	Light-Duty Gasoline Vehicles – All gasoline-powered passenger cars	36
LDDV	Light-Duty Diesel Vehicles – All diesel-powered passenger cars	1
LDGT	Light-Duty Gasoline Trucks – All smaller gasoline-powered trucks (0 to 8,500 lbs. GVWR)	54
LDDT	Light-Duty Diesel Trucks (LDDT) – All smaller diesel-powered trucks (0 to 8,500 lbs. GVWR)	1
HDGV	Heavy-Duty Gasoline Vehicles (HDGV) – All larger gasoline-powered vehicles (8,501 to >60,000 lbs. GVWR)	4
HDDV	Heavy-Duty Diesel Vehicles – All larger diesel-powered vehicles (10,001 to >60,000 lbs. GVWR)	3
MC	Motorcycles (MC) – All motorcycles (assumed to be gasoline powered)	1

Next, the number of vehicles which fall under each vehicle category are calculated under the assumption that the fleet mix for the unregistered vehicles is the same as for the registered

vehicles. By slightly modifying Equation 5-7, the number of vehicles for each category (n_i) may be derived from the total number of vehicles (N) and vehicle category mix (MIX_i).

$$n_i = N \times \frac{MIX_i}{100}$$

$$n_{LDGV} = 1,800 \times \frac{36\%}{100\%} = \mathbf{648 \text{ Vehicles}}$$

$$n_{LDDV} = 1,800 \times \frac{1\%}{100\%} = \mathbf{18 \text{ Vehicles}}$$

$$n_{LDGT} = 1,800 \times \frac{54\%}{100\%} = \mathbf{972 \text{ Vehicles}}$$

$$n_{LDDT} = 1,800 \times \frac{1\%}{100\%} = \mathbf{18 \text{ Vehicles}}$$

$$n_{HDGV} = 1,800 \times \frac{4\%}{100\%} = \mathbf{72 \text{ Vehicles}}$$

$$n_{HDDV} = 1,800 \times \frac{3\%}{100\%} = \mathbf{54 \text{ Vehicles}}$$

$$n_{MC} = 1,800 \times \frac{1\%}{100\%} = \mathbf{18 \text{ Vehicles}}$$

Next, the average annual vehicle miles traveled (AVM_i) is calculated. Using the data provided in the form above, the AVM traveled is calculated as follows:

$$AVM_i = \frac{52 \text{ weeks}}{\text{yr}} \times \left[\left(\frac{75\%}{100\%} \times 6 \frac{\text{mi}}{\text{day}} \times 5 \frac{\text{day}}{\text{week}} \right) + \left(\frac{50\%}{100\%} \times 4 \frac{\text{mi}}{\text{day}} \times 2 \frac{\text{day}}{\text{week}} \right) \right]$$

$$AVM_i = \frac{52 \text{ weeks}}{\text{yr}} \times \left[\left(0.75 \times 6 \frac{\text{mi}}{\text{day}} \times 5 \frac{\text{day}}{\text{week}} \right) + \left(0.5 \times 4 \frac{\text{mi}}{\text{day}} \times 2 \frac{\text{day}}{\text{week}} \right) \right]$$

$$AVM_i = \frac{52 \text{ weeks}}{\text{yr}} \times \left[\left(22.5 \frac{\text{mi}}{\text{week}} \right) + \left(4 \frac{\text{mi}}{\text{week}} \right) \right]$$

$$AVM_i = \frac{52 \text{ weeks}}{\text{yr}} \times \left[\left(26.5 \frac{\text{mi}}{\text{week}} \right) \right] = \mathbf{1,378 \frac{\text{mi}}{\text{yr}}}$$

Finally, the total annual VMT for each category (VMT_i) is calculated using Equation 5-7.

$$VMT_i = AVM_i \times n_i$$

$$VMT_{LDGV} = 1378 \frac{\text{mi}}{\text{yr}} \times 648 \text{ vehicles} = \mathbf{892,944 \frac{\text{mi}}{\text{yr}}}$$

$$VMT_{LDDV} = 1378 \frac{\text{mi}}{\text{yr}} \times 18 \text{ vehicles} = \mathbf{24,804 \frac{\text{mi}}{\text{yr}}}$$

$$VMT_{LDGT} = 1378 \frac{mi}{yr} \times 972 \text{ vehicles} = 1,339,416 \frac{mi}{yr}$$

$$VMT_{LDDT} = 1378 \frac{mi}{yr} \times 18 \text{ vehicles} = 24,804 \frac{mi}{yr}$$

$$VMT_{HDGV} = 1378 \frac{mi}{yr} \times 72 \text{ vehicles} = 99,216 \frac{mi}{yr}$$

$$VMT_{HDDV} = 1378 \frac{mi}{yr} \times 54 \text{ vehicles} = 74,412 \frac{mi}{yr}$$

$$VMT_{MC} = 1378 \frac{mi}{yr} \times 18 \text{ vehicles} = 24,804 \frac{mi}{yr}$$

Step 3 – Select emission factors. EFs for vehicles in CY2024 are provided in Table 5-19. The CO EFs for a base in Alabama for 2024 are provided in the sub-table below.

Vehicle Category	CO Emission Factor (g/mi)
LDGV	4.527
LDGT	4.089
HDGV	11.927
LDDV	5.385
LDDT	5.362
HDDV	1.592
MC	12.896

Step 4 – Calculate emissions. Emissions are calculated using the vehicle miles traveled as calculated in Step 2, the EFs recorded in Step 3, and Equation 5-6. First, the CO emissions from each vehicle category are individually calculated and then summed for total CO emissions. Also, since no information was provided regarding the use of alternative fuels, a FERF value of “0” is used.

$$E(Pol)_{Total} = \sum_{i=1}^n \left[VMT_i \times EF(Pol)_i \times \frac{FERF(Pol)}{100} \times 0.002205 \right]$$

$$E(CO)_{LDGV} = 892,944 \frac{mi}{yr} \times 4.527 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 8,913.40 \frac{lb}{yr}$$

$$E(CO)_{LDDV} = 24,804 \frac{mi}{yr} \times 4.089 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 223.64 \frac{lb}{yr}$$

$$E(CO)_{LDGT} = 1,339,416 \frac{mi}{yr} \times 11.927 \frac{g}{mi} \times \left[1 - \frac{0\%}{100\%} \right] \times 0.002205 \frac{lb}{g} = 35,225.35 \frac{lb}{yr}$$

$$E(CO)_{LDDT} = 24,804 \frac{\text{mi}}{\text{yr}} \times 5.385 \frac{\text{g}}{\text{mi}} \times \left[1 - \frac{0\%}{100\%}\right] \times 0.002205 \frac{\text{lb}}{\text{g}} = 294.52 \frac{\text{lb}}{\text{yr}}$$

$$E(CO)_{HDGV} = 99,216 \frac{\text{mi}}{\text{yr}} \times 5.362 \frac{\text{g}}{\text{mi}} \times \left[1 - \frac{0\%}{100\%}\right] \times 0.002205 \frac{\text{lb}}{\text{g}} = 1,173.05 \frac{\text{lb}}{\text{yr}}$$

$$E(CO)_{HDDV} = 74,412 \frac{\text{mi}}{\text{yr}} \times 1.592 \frac{\text{g}}{\text{mi}} \times \left[1 - \frac{0\%}{100\%}\right] \times 0.002205 \frac{\text{lb}}{\text{g}} = 261.21 \frac{\text{lb}}{\text{yr}}$$

$$E(CO)_{MC} = 24,804 \frac{\text{mi}}{\text{yr}} \times 12.896 \frac{\text{g}}{\text{mi}} \times \left[1 - \frac{0\%}{100\%}\right] \times 0.002205 \frac{\text{lb}}{\text{g}} = 705.32 \frac{\text{lb}}{\text{yr}}$$

The total CO emissions are calculated by summing the CO emissions from each contributing vehicle category as shown:

$$E(Pol)_{Total} = \sum_{i=1}^n E(Pol)_i$$

$$E(CO)_{Total} = (8,913.40 + 223.64 + 35,225.35 + 294.52 + 1,173.05 + 261.21 + 705.32) \frac{\text{lb}}{\text{yr}}$$

$$E(CO)_{TOTAL} = 46,796.49 \frac{\text{lb}}{\text{yr}}$$

5.5.4 Problem 4 – Calculating POV Emissions Using Method 3

A DAF base is interested in determining the NO_x generated by the operation of POVs driven on base. There are approximately 600 POVs that average 3,700 miles per year, but no vehicle studies have been conducted to describe the vehicle mix. Using the typical DAF vehicle mix, determine the NO_x generated by the operation of these vehicles on base for CY 2024. The base is in Colorado.

Step 1 – Gather fleet data. The problem statement provided information regard the number of POVs (**N=600**) and the average vehicle miles driven by each vehicle (**AVM = 3,700 miles per year**).

Step 2 – Group vehicle categories. The first step is to determine the total annual vehicle miles traveled (VMT_{Total}) for all vehicles. The problem statement provided information regarding the average vehicle miles traveled for all POVs (AVM), but not the average miles traveled for each vehicle category (AVM_i). Therefore, the appropriate method for calculating the total annual vehicle miles traveled for all vehicles utilizes Equation 5-4 as shown:

$$VMT_{Total} = AVM \times N$$

$$VMT_{Total} = 3,700 \frac{mi}{yr} \times 600 = 2,220,000 \frac{mi}{yr}$$

Since the typical vehicle mix is assumed for this example, the vehicle mix (MIX_i) for each category for POVs has been extracted from Table 5-2 and presented in the following table.

Vehicle Category	POV Vehicle Mix (%)
LDGV	41.00
LDDV	0.52
LDGT	46.4
LDDT	0.66
HDGV	3.39
HDDV	2.51
MC	1.88
LDGV (H)	0.09
LDGT (H)	0.09
LDGV (V)	2.14
LDGT (V)	1.32

Step 3 – Select emission factors. The EFs for CY 2024 POVs are presented in Table 5-19. The EFs for NO_x in Colorado have been extracted from the table and presented in the table below.

Vehicle Category	NO _x Emission Factor (g/mi)
LDGV	0.168
LDDV	0.224
LDGT	0.754
LDDT	0.148
HDGV	0.492
HDDV	2.745
MC	0.758

Step 4 – Calculate emissions. First, a total composite EF is calculated by taking the product of the EF for each vehicle category (EF(Pol)_i) – from the table in Step 3 above), the vehicle mix value for the corresponding vehicle category (MIX_i – from the table in Step 2), and the appropriate FERF from Table 5-7. FERF for electric vehicles are assumed to be 100%. These values are calculated as follows:

$$EF(Pol)_{Total} = \sum_{i=1}^n \left\{ EF(Pol)_i \times \frac{MIX_i}{100} \times \left[1 - \frac{FERF(Pol)}{100} \right] \right\}$$

$$EF(NO_X)_{LDGV} = 0.168 \frac{g}{mi} \times \left(\frac{41.00\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.0689 \frac{g}{mi}}$$

$$EF(NO_X)_{LDDV} = 0.224 \frac{g}{mi} \times \left(\frac{0.52\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.0012 \frac{g}{mi}}$$

$$EF(NO_X)_{LDGT} = 0.754 \frac{g}{mi} \times \left(\frac{46.4\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.350 \frac{g}{mi}}$$

$$EF(NO_X)_{LDDT} = 0.148 \frac{g}{mi} \times \left(\frac{0.66\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.001 \frac{g}{mi}}$$

$$EF(NO_X)_{HDGV} = 0.492 \frac{g}{mi} \times \left(\frac{3.39\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.017 \frac{g}{mi}}$$

$$EF(NO_X)_{HDDV} = 2.51 \frac{g}{mi} \times \left(\frac{2.745\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.069 \frac{g}{mi}}$$

$$EF(NO_X)_{MC} = 0.758 \frac{g}{mi} \times \left(\frac{1.88\%}{100\%} \right) \times \left[1 - \frac{0\%}{100\%} \right] = \mathbf{0.014 \frac{g}{mi}}$$

$$EF(NO_X)_{LDGV(H)} = 0.168 \frac{g}{mi} \times \left(\frac{0.09\%}{100\%} \right) \times \left[1 - \frac{75\%}{100\%} \right] = \mathbf{0.00004 \frac{g}{mi}}$$

$$EF(NO_X)_{LDGT(H)} = 0.754 \frac{g}{mi} \times \left(\frac{0.09\%}{100\%} \right) \times \left[1 - \frac{75\%}{100\%} \right] = \mathbf{0.0002 \frac{g}{mi}}$$

$$EF(NO_X)_{LDGV(V)} = 0.168 \frac{g}{mi} \times \left(\frac{2.14\%}{100\%} \right) \times \left[1 - \frac{100\%}{100\%} \right] = \mathbf{0.00 \frac{g}{mi}}$$

$$EF(NO_X)_{LDGT(V)} = 0.754 \frac{g}{mi} \times \left(\frac{1.32\%}{100\%} \right) \times \left[1 - \frac{100\%}{100\%} \right] = \mathbf{0.00 \frac{g}{mi}}$$

Next, sum these values for a total composite emission factor ($EF(Pol)_{Total}$) as shown:

$$EF(Pol)_{Total} = \sum_{i=1}^n EF(Pol)_i$$

$$EF(NO_X)_{Total} = (0.0689 + 0.0012 + 0.350 + 0.001 + 0.017 + 0.069 + 0.014 + 0.00004 + 0.002 + 0.00 + 0.00) \frac{g}{mi} = \mathbf{0.523 \frac{g}{mi}}$$

Finally, using the total vehicle miles traveled (VMT_{Total}) from Step 2, and the total composite EF, the total NO_X emissions are calculated using Equation 5-8 as shown:

$$E(Pol)_{Total} = VMT_{Total} \times EF(Pol)_{Total} \times 0.002205$$

$$E(NO_X)_{Total} = 2,220,000 \frac{mi}{yr} \times 0.523 \frac{g}{mi} \times 0.002205 \frac{lb}{g}$$

$$E(NO_X)_{Total} = 2,560.14 \frac{lb}{yr}$$

5.5.5 Problem 5 – Calculating Fugitive PM Emissions

Determine the fugitive PM₁₀ generated from the POVs and GOVs provided in Problem 1 given that the base is in central Alabama. It can be assumed that 100% of all miles traveled by POVs are on paved roads, whereas GOVs traveled 90% on paved roads and 10% on unpaved roads.

Step 1 – Gather fleet data. Calculation of fugitive PM₁₀ emissions from on-road vehicle operation requires that the total vehicle miles driven (VMT_{Total}) for POVs and GOVs is known. These values have been calculated in Step 1 of Problem 1: **VMT_{Total-POV} = 1,925,586** and **VMT_{Total-GOV} = 173,394 miles/year**.

Step 2 – Select emission factors. Fugitive PM₁₀ EFs are provided in Table 5-8. For POVs, the EFs for paved and unpaved roads are **0.058** and **466.206 g/mi**, respectively. Similarly, for GOVs, the EFs for paved and unpaved roads are **0.069** and **505.981 g/mi**, respectively.

Once selected, the EFs must be corrected to account for precipitation at the base. It is given that the base is in central Alabama. Based on this information, a review of Figure 5-1 reveals that the base is estimated to have 110 days in the year with precipitation of 0.01 inches or more. The EFs are corrected using this value and Equation 5-1 or Equation 5-2.

For POVs:

$$EF(Pol)_{CP} = EF(Pol)_P \times \left(1 - \frac{P}{4N}\right)$$

$$EF(PM_{10})_{CP} = 0.058 \frac{g}{mi} \times \left(1 - \frac{110}{4 \times 365}\right)$$

$$EF(PM_{10})_{CP} = 0.058 \frac{g}{mi} \times \left(1 - \frac{110}{1460}\right) = \mathbf{0.054 \frac{g}{mi}}$$

For GOVs:

$$EF(PM_{10})_{CP} = 0.069 \frac{g}{mi} \times \left(1 - \frac{110}{4 \times 365}\right)$$

$$EF(PM_{10})_{CP} = 0.069 \frac{g}{mi} \times \left(1 - \frac{110}{1460}\right) = \mathbf{0.064 \frac{g}{mi}}$$

$$EF(Pol)_{CU} = EF(Pol)_U \times \left(1 - \frac{P}{N}\right)$$

$$EF(PM_{10})_{CU} = 505.981 \frac{g}{mi} \times \left(1 - \frac{110}{365}\right) = \mathbf{353.494 \frac{g}{mi}}$$

Step 3 – Calculate emissions. Using the VMT_{Total} for POVs and GOVs as recorded in Step 1, the estimated percentage of driving on paved and unpaved roads (as given in the problem statement), and Equation 5-17, emissions are calculated as follows:

$$E(Pol)_{Total} = VMT_{Total} \times \left[\left(\frac{\%VMT_P}{100} \times EF(Pol)_{CP} \right) + \left(\frac{\%VMT_U}{100} \times EF(Pol)_{CU} \right) \right] \times 0.002205$$

For POVs:

$$E(PM_{10})_{Total} = 1,925,586 \frac{mi}{yr} \times \left[\left(\frac{100\%}{100\%} \times 0.054 \frac{g}{mi} \right) + (0) \right] \times 0.002205 \frac{lb}{g}$$

$$E(PM_{10})_{Total} = 1,925,586 \frac{mi}{yr} \times \left[\left(1 \times 0.054 \frac{g}{mi} \right) \right] \times 0.002205 \frac{lb}{g}$$

$$\boxed{E(PM_{10})_{Total} = \mathbf{229.28 \frac{lb}{yr}}}$$

For GOVs:

$$E(PM_{10})_{Total} = 173,394 \frac{mi}{yr} \times \left[\left(\frac{90\%}{100\%} \times 0.064 \frac{g}{mi} \right) + \left(\frac{10\%}{100\%} \times 353.494 \frac{g}{mi} \right) \right] \times 0.002205 \frac{lb}{g}$$

$$E(PM_{10})_{Total} = 173,394 \frac{mi}{yr} \times \left[\left(0.9 \times 0.064 \frac{g}{mi} \right) + \left(0.1 \times 353.494 \frac{g}{mi} \right) \right] \times 0.002205 \frac{lb}{g}$$

$$E(PM_{10})_{Total} = 173,394 \frac{mi}{yr} \times \left[\left(0.0576 \frac{g}{mi} \right) + \left(35.3494 \frac{g}{mi} \right) \right] \times 0.002205 \frac{lb}{g}$$

$$E(PM_{10})_{Total} = 173,394 \frac{mi}{yr} \times \left[35.407 \frac{g}{mi} \right] \times 0.002205 \frac{lb}{g}$$

$$\boxed{E(PM_{10})_{Total} = 13,537.29 \frac{lb}{yr}}$$

Notes for Table 5-39 through Table 5-43.

The values in the NH₃ column reflect statewide values as calculated by MOVES4 for the state of California due to EMFAC lacking NH₃ as a pollutant output.

6.0 FUEL TRANSFER (FDSP, FLD) – EXCLUDES ON-ROAD VEHICLE REFUELING

- *Fugitive Source*
- *Mobile Source* – When fuel is dispensed to mobile equipment.
- *Stationary Source* – Fuel spills and when dispensed to stationary equipment.

***The DAF recommends that most emissions generated during the transfer (dispensing) of fuel into *on-road* vehicles be classified as mobile emissions. However, if the regulator insists this category be included as a stationary source, subtract those emissions from the Mobile AEI, and add them to the Stationary AEI to avoid duplicate reporting. This is accomplished by manually calculating emissions generated from on-road vehicle refueling using the procedures given in this section, then subtracting those values from the emissions generated by on-road vehicles covered in the previous section. ***

6.1 Introduction

Fuel transfer includes the dispensing of fuel into non-road engines and equipment, aircraft, and fuel trucks. **Note that the emissions from the refueling of *VEHEs* are not addressed here since those emissions are accounted for in the EFs generated by the MOVES4 model as explained in the previous chapter.** Emissions from fuel dispensing are the result of vapors being displaced as fuel is added to the fuel tank. The amount of vapor released to the atmosphere is a function of the gas and fuel tank temperatures, the vapor pressure of the fuel, the dispensing rate, and the presence of vapor emission control devices. **The vapor that is emitted into the atmosphere is composed of both VOCs and HAPs and is considered fugitive in nature.**

Minor fuel spills are an inevitable consequence of fuel dispensing. Typically, these spills are individually insignificant though may collectively result in a substantial release of VOC and HAP emissions. **Emissions from minor spills are accounted for in the “Fuel Transfer” section of the Stationary Guide to produce a conservative emissions calculation. Emissions from significant spills, which are those spills that are reported to the Environmental or Civil Engineering Environmental office, are not addressed here but described in the “Fuel Spills” section of the Transitory Guide.** The vapor emissions of concern from fuel dispensing operations are described by the simple control volume given in Figure 6-1.

Figure 6-1. Simple Fuel Dispensing Control Volume

The loading method used in the fuel transfer process has a significant effect on the amount of vapor emissions generated during the transfer activity. There are two main fuel loading methods: splash loading and submerged loading. The splash loading method involves the lowering of the fill pipe into the tank and **above the liquid level**. The loading of the fuel using the splash method results in significant turbulence, which increases the amount of vapor released into the atmosphere. The alternative method, submerged loading, may be further subdivided into two techniques: the submerged fill pipe method and the bottom-loading method. In the submerged fill pipe method, the fill pipe extends almost to the bottom of the storage tank. In the bottom loading method, a fill pipe is permanently attached to the bottom of the storage tank. In both cases, the fill pipe is **below the liquid level**. Therefore, turbulence is minimized, and vapor emissions are greatly reduced when compared to the splash loading method. Each method is shown in Figure 6-2.

Figure 6-2. Splash Loading, Submerged Fill Pipe, and Bottom Loading Methods

There are several challenges to calculating evaporative emissions from fuel transfer activities. These challenges include the use of several different fuels used on base, such as gasoline, diesel, or JP-8 fuel, and their different vapor pressures. Furthermore, there are multiple destinations for fuels on base that may make it more difficult to gather data or determine what emissions are classified as mobile or stationary. To simplify how each base should calculate fuel transfer emissions, a diagram of the typical transfer methods and destinations of fuel on base is provided in Figure 6-3.

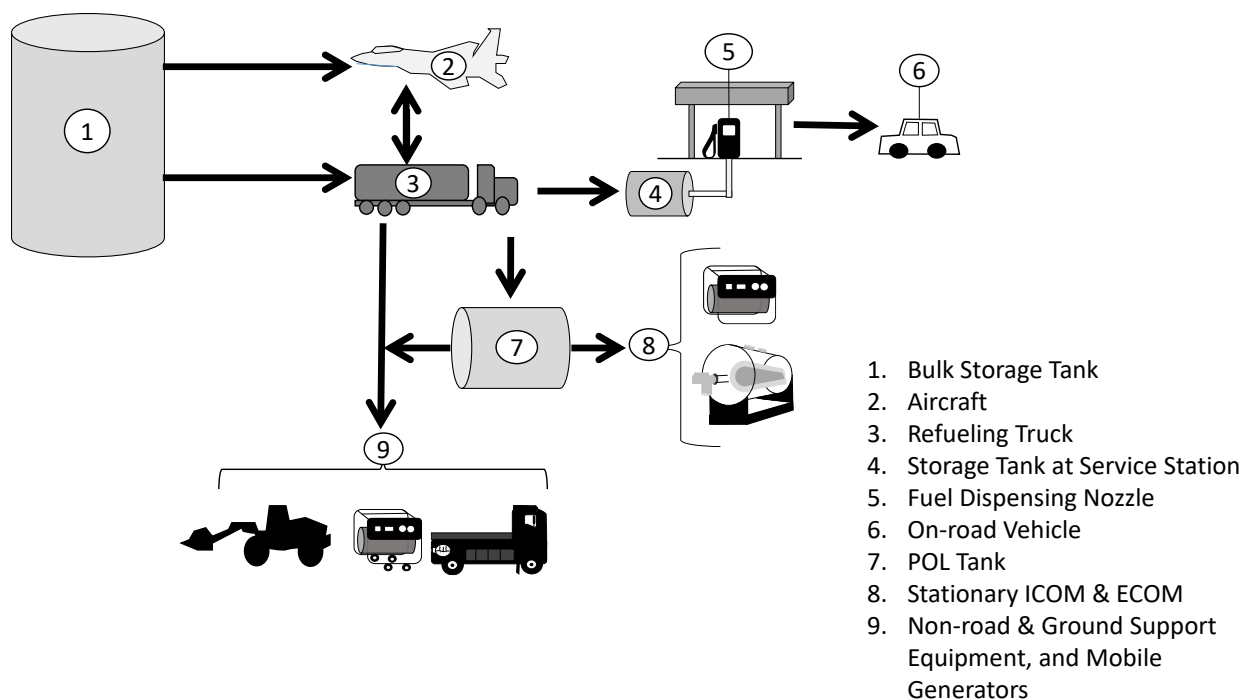

Figure 6-3. Typical On-Base Fuel Transfer Activities and Destinations

Figure 6-3 shows the typical fuel transfer paths that fuel may go through at a DAF installation. The transfer of the fuel into different equipment results in the generation and release of pollutant emissions. The classification (mobile vs. stationary) of this equipment determines whether the generated emissions are regarded as mobile or stationary source emissions. It is important to note that **significant** fuel spills may occur at any point in the fuel transfer process, which will contribute to VOC and HAP emissions as the fuel evaporates. However, since these are uncommon occurrences, emissions from fuel spills are addressed in the *Air Emissions Guide for Air Force Transitory Sources*. The specific pathways illustrated in Figure 6-3 are described below and categorized as either mobile (shaded) or stationary (not shaded) sources of emissions.

1 (Bulk Storage Tank) → 2 (Aircraft)

The figure above illustrates fuel transferred to refuel an aircraft from a bulk storage tank via a hydrant system. The vapors displaced within the storage tank as the liquid level lowers or rises are known as “working losses.” The vapors generated in the space above the stored liquid are known as “breathing losses.” These are **stationary emissions** and are calculated using the equations provided in Chapter 7 of AP-42. Refer to the *Air Emissions Guide for Air Force Stationary Sources* for more information regarding the calculation of these emissions.

Mobile emissions are generated from the displaced vapor in the aircraft fuel tank. These emissions should be reported in the mobile AEI and are calculated as described later in this chapter.

1 (Bulk Storage Tank) → 3 (Refueling Truck)

The **stationary source of emissions** is the bulk storage tank producing working losses and breathing losses from the liquid fuel. The methodology for calculating these emissions is provided in the *Air Emissions Guide for Air Force Stationary Sources*.

The **mobile emissions** from loading fuel into refueling trucks are generated from the displaced vapor in the fuel truck. These emissions should be reported in the mobile AEI and are calculated as described later in this chapter.

2 (Refueling Truck) ↔ 3 (Aircraft)

The figure above illustrates the fueling and defueling of aircraft via a refueling truck. Both pieces of equipment are classified as **mobile**, therefore all emissions generated from these activities should be reported in the mobile AEI and are calculated as described later in this chapter. Emissions from both mobile pieces of equipment come from displaced vapors in the refueling truck and aircraft fuel tanks.

3 (Refueling Truck) → 4 (Storage Tank and Service Station)

The figure above illustrates the loading of a refueling truck into a storage tank at a fuel service station. The **stationary emissions** from refilling of a storage tank at a fuel dispensing location include breathing and working losses from the storage tank. The methodology for calculating these emissions is provided in the *Air Emissions Guide for Air Force Stationary Sources*.

The only substantial **mobile emissions** from the fueling of the tank via the refueling truck are generated from any significant fuel spills which are addressed in the *Air Emissions Guide for Air Force Transitory Sources*.

5 (Fuel Dispensing Nozzle) → 6 (On-Road Vehicle)

The figure above illustrates the refueling of a vehicle at a service station. The **stationary emissions** are the result of the evaporation of spilled fuel from the fuel nozzle whose calculations are described in the *Air Emissions Guide for Air Force Stationary Sources*.

The **mobile emissions** are generated from the displaced vapors in the vehicle fuel tank. The displaced vapor emissions should be included in a mobile AEI and are already accounted for in the MOVES model used to calculate VEHE emissions. AP-42 states that the motor vehicle refueling emissions equation is incorporated into the MOBILE model, which has been integrated into the MOVES model. The MOVES4 model is the model used for estimating emissions for VEHEs. This version of the model allows for disabling the refueling emissions calculations if these emissions are included in a stationary AEI, rather than in a mobile AEI. **This should only be done if the regulator insists that this category be included as a stationary source. Otherwise, these emissions are already accounted for in the EFs found in the “ON-ROAD VEHICLES (VEHE)” chapter of this guide.**

3 (Refueling Truck) → 7 (POL Tank) This fuel transfer pathway illustrates the loading of fuel from a refueling truck into a Petroleum, Oil, and Lubricants (POL) storage tank. The **stationary emissions** include the breathing and working losses from smaller storage tanks on base. The methodology for calculating these emissions is provided in the *Air Emissions Guide for Air Force Stationary Sources*.

Likely, the only **mobile emissions** generated from this pathway are from any significant fuel spills associated with the refueling truck (a mobile source). Such emissions would be considered transitory in nature and are addressed in the *Air Emissions Guide for Air Force Transitory Sources*.

7 (POL Tank) → 8 (Stationary ICOM/ECOM) The figure above illustrates the loading of fuel from a storage tank into a stationary Internal Combustion (ICOM) equipment, such as a generator, or External Combustion (ECOM) equipment, such as a boiler. The **stationary emissions** from the fuel outlet (of the storage tank) are the result of any significant fuel spills and breathing or working losses. The breathing/working losses are calculated using the methodology described in Chapter 7 of AP-42 while emissions from significant fuel spills are described in the *Air Emissions Guide for Air Force Transitory Sources*. The **stationary emissions** from the fuel loading inlet (of the stationary ICOM or ECOM unit) are generated from the displaced vapor in the fuel tanks. The methodology for calculating these emissions is provided in the *Air Emissions Guide for Air Force Stationary Sources*.

7 (POL Tank) → 9 (Non-Road & Ground Support Equipment / Mobile Generators)

During this fuel transfer process, fuel is moved from a storage tank to a mobile piece of equipment, such as non-road equipment, Ground Support Equipment (GSE), or a mobile generator. The **stationary emissions** from the storage tank are the result of any significant fuel spills and the working and breathing losses from the tank. The methodology for calculating these emissions is provided in Chapter 7 of AP-42 and in the *Air Emissions Guide for Air Force Stationary Sources*, while fuel spill emissions are addressed in the *Air Emissions Guide for Air Force Transitory Sources*.

The **mobile emissions** from the fuel loading inlet (of the non-road and ground support equipment or mobile generator) are produced by the displaced vapor in the fuel tanks and should be reported in a mobile AEI. Emissions are calculated as described later in this chapter.

3 (Refueling Trucks) → 9 (Non-Road & Ground Support Equipment / Mobile Generators)

The figure illustrates the transfer of fuel from a mobile fuel loading outlet (refueling truck) into either non-road equipment, GSE, or a mobile generator, **all of which are considered mobile sources**. These emissions should be reported in a mobile AEI, the calculation methodology for which is described later in this chapter.

6.2 Emission Factors

Section 5.2 of AP-42 describes both the emissions from the loading of fuel into fuel trucks and the evaporative emissions from the fueling of a gasoline vehicle. Since the emissions from fueling gasoline vehicles is covered in the MOVES4 model, the EFs for vehicle refueling are not provided here, but may be found in Table 5.2-7 of AP-42. For non-road engines and fuel trucks, the most appropriate method for calculating emissions from fuel dispensing is to calculate the loading loss. The loading loss is the primary source of evaporative emissions from the loading of fuel. These losses are the result of organic vapors within a fuel tank that are displaced into the atmosphere as the tank is loaded with fuel. To calculate these losses, the saturation factor, vapor pressure of the fuel molecular weight of the vapors, and the temperature of the bulk liquid must be known. A detailed description of how to calculate these losses is provided in the next section.

The saturation factor refers to the ratio of the saturated value of the expelled vapor to the unsaturated value. These values vary based on the method of fuel loading. A tank that is filled with only one fuel, or fuels with similar characteristics, is said to be practicing “dedicated normal service.” When loading vapors are returned to the loading terminal after the fuel is unloaded to a storage tank, it is known as “dedicated vapor balance service.” Section 5.2 of AP-42 provides the saturation factors, which are included below in Table 6-1.

Table 6-1. Fuel Loading Saturation Factors

Loading Method	Loading Parameters	S Factor
Submerged Loading	Clean Tank	0.50
	Dedicated Normal Service	0.60
	Dedicated Vapor Balance Service	1.00
Splash Loading	Clean Tank	1.45
	Dedicated Normal Service	1.45
	Dedicated Vapor Balance Service	1.00

SOURCE: U.S. EPA. “Transportation and Marketing of Petroleum Liquids.” *Compilation of Air Pollutant Emission Factors – Volume I: Stationary Point and Area Sources*. Fifth Edition. 1995. Section 5.2.

The vapor emissions resulting from fuel transfer is a function of the vapor pressure of the fuel. The vapor pressure is indicative of the evaporation rate of a liquid. Vapor pressures for select fuels and their respective vapor molecular weights are provided in Table 6-2.

Table 6-2. Vapor Pressures for Various Fuels

Petroleum Liquid	Vapor Molecular Weight (lb/lb-Mol)	True Vapor Pressure (psia)

6.3 Control and Capture Efficiencies

Emissions from fuel dispensing may be controlled using a variety of techniques. Estimating emissions in which a control device is utilized is more challenging since the capture efficiency must also be considered. Additionally, since portions of fuel transfer are regarded as either stationary or mobile sources, using the control and capture efficiencies appropriately may be confusing. For example, in Step 1-2 from Figure 6-3, fuel is loaded from a loading terminal storage tank and into a fuel truck. The displaced vapor may be captured with a blower system and run through a vapor recovery unit before being returned to the storage tank. In this case, the capture efficiency of the truck and the control efficiency of the vapor recovery unit are used to determine the emissions from this process. The control efficiency is taken from the stationary

unit, although the emissions are classified as mobile since the emissions are the result of displaced vapor in the mobile fuel truck. Typical capture and control efficiencies can be found in Table 6-3 and Table 6-4 respectively.

Table 6-3. Typical Fuel Truck Capture Efficiencies

Fuel Truck Capture System	Capture Efficiency (%)
Untested	70.0
EPA standards (NSPS Subpart XX) leak test	98.7
MACT-level annual leak test	99.2
Trucks with installed blower system	100.0 ^a

- Flares must meet 40 CFR 60.18 requirements of minimum heating value of waste gas and a maximum flare tip velocity.
- Must be designed for the variability of the waste gas stream and basic monitoring which consists of a temperature monitor that indicates the device is achieving a satisfactory minimum temperature.
- Must have an alarm system that will prevent break through.

Alternatively, EFs for the loading of fuel trucks have been developed for several fuels likely to be distributed on base. These EFs are based on an assumed temperature of 60°F and may be used as an alternative to calculate the loading loss. Table 5.2-5 of AP-42 provides these EFs, which have been reproduced here in Table 6-5.

6.4 Emission Calculations

Emissions of concern from fuel transfer operations are VOCs and HAPs. The volumes of VOCs and HAPs emitted are related to the amount of VOC and HAP constituents within the fuel. Calculations of emissions of VOCs and HAPs from fuel transfer are outlined below.

6.4.1 VOC Emissions Calculations (Preferred Method)

The preferred method for calculating VOC emissions from the transfer of fuel is to use the fuel vapor pressure, saturation factor, temperature, and total throughput to estimate the loading loss. VOCs are calculated as follows:

$$E(VOC) = Q \times \frac{1}{1000} \times 12.46 \times \frac{S \times P \times M}{T} \times \left\{ 1 - \left[\left(\frac{Cap}{100} \right) \times \left(\frac{CE}{100} \right) \right] \right\}$$

Equation 6-1

Where,

- E(VOC)** = Annual emissions of VOCs (lb/yr)
- Q** = Annual quantity of fuel transferred (gal/yr)
- 1000** = Factor converting gallons to 10³ gallons (gal/10³ gal)
- 12.46** = Equation constant (°R lb-mol/psia 10³ gal)
- S** = Saturation factor. Provided in Table 6-1
- P** = True vapor pressure of fuel (psia). Provided in Table 6-2
- M** = Vapor molecular weight of the fuel (lb/lb-mol). (Table 6-2)
- T** = Temperature of bulk liquid loaded (°R)
- Cap** = Capture efficiency of the loading terminal (%). (Table 6-3)
- CE** = Efficiency of the control device (%). Provided in Table 6-4
- 100** = Factor for converting a percent to a fraction (%)

A detailed control volume outlining the emissions from fuel transfer operations is provided in Figure 6-4.

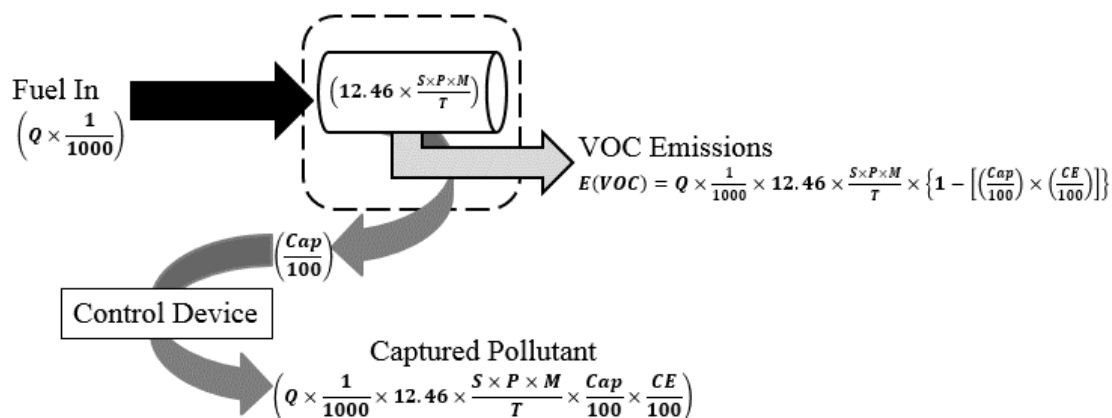

Figure 6-4. Fuel Transfer Control Volume – Preferred Method

6.4.2 VOC Emissions Calculations (Emission Factor Alternative Method)

Using the EF method, the appropriate EF selected from Table 6-5 and the total quantity of fuel transferred, the emissions are calculated as follows:

$$E(VOC) = Q \times \frac{1}{1000} \times EF(VOC) \times \left\{1 - \left[\left(\frac{Cap}{100}\right) \times \left(\frac{CE}{100}\right)\right]\right\}$$

Equation 6-2

Where,

EF(VOC)= VOC emission factor as provided in Table 6-5 (lb/10³ gal)

A detailed control volume is provided in Figure 6-5.

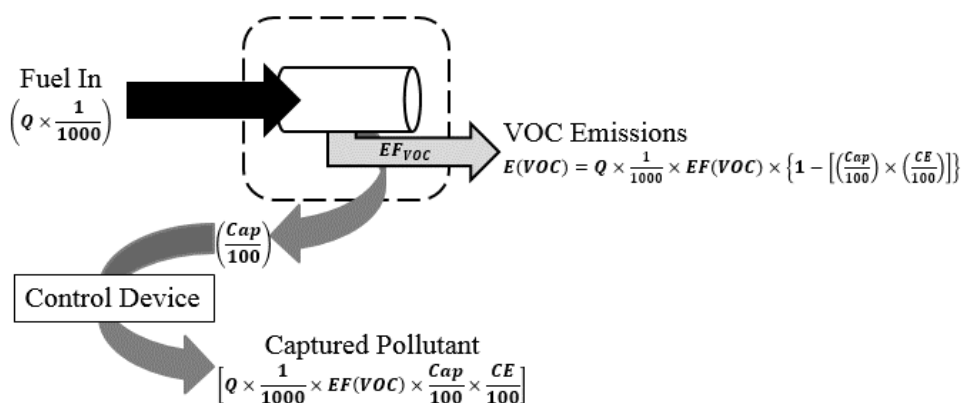

Figure 6-5. Fuel Transfer Control Volume – Emission Factor Method

6.4.3 HAP Emissions Calculation

The number of HAPs released into the environment from fuel transfer operations may be estimated using the total VOCs emitted, as calculated above, and the weight percent of HAPs in the fuel itself (APIMS and the Air Conformity Applicability Model, or ACAM, automatically calculate these values). Contact the fuel supplier for specific information regarding the weight percent of HAPs in fuels commonly used at DAF installations. In the absence of available data, Table 6-6 provides the typical weight percent of individual HAPs found in several fuels used at DAF installations. Using the total VOCs and weight percent HAP in the fuel, the total HAP emissions from fuel transfer operations is calculated using Equation 6-3 below.

$$E(HAP) = E(VOC) \times \frac{WP(HAP)}{100}$$

Equation 6-3

Where,

E(HAP)	=	HAP emissions from fuel dispensing (lb/yr)
WP(HAP)	=	Weight percent HAP in the fuel (%)

Table 6-6. Weight Percent of HAPs in Fuels commonly used at Air Force Installations

Compound	Molecular Weight	Vapor Pressure (psi) ^a	Typical wt. %

a. Based on gasoline with a Reid Vapor Pressure of 10.

b. Based on temperature of 70°F

c. SOURCE: “JP-8 Volatility Study,” Southwest Research Institute (SWRI), March 2001. Vapor pressures calculated using the composite data calculations, an average flash point temperature of 118.238°F, and atmospheric pressure of 760mmHg. Flash point temperature average provided by “Petroleum Quality Information System Fuels Data (2005),” Defense Logistics Agency (DLA), Defense Energy Support Center, Technology and Standardization Division, 2006.

6.5 Information Resources

Information regarding the annual fuel throughput may be collected from the fuel service station supervisor. The supervisor may also be able to provide specific information regarding the fuel vapor pressure and HAP constituent data. If this information is unavailable, contact the fuel supplier to gather this data for more precise emissions calculations.

6.6 Example Problems

6.6.1 Problem 1 – Preferred Method

A total of 150,000 gal of gasoline and 85,000 gal of diesel were dispensed from a POL tank into non-road equipment during the previous year. Based on the location of the installation, the gasoline used has an average Reid Vapor Pressure (RVP) of 10 and the average fuel temperature at the installation is 60°F. Calculate the total VOCs and xylene emissions.

Step 1 – Convert the temperature to the correct units. The temperature was given in terms of °F; however, to calculate the EFs needed, the temperature must be converted to the correct units (degrees Rankin [°R]) as follows:

$$T(^{\circ}R) = T(^{\circ}F) + 460.67$$

$$T(^{\circ}R) = 60 + 460.67 = 520.67^{\circ}R$$

Step 2 – Record the vapor pressures and vapor molecular weights. These values are needed for EF calculations and are given in Table 6-2. For RVP 10 gasoline, the molecular weight and

vapor pressure at 60°F are given as **66 lb/lb-mol** and **5.20 psia**, respectively. Similarly, for diesel, the vapor molecular weight and vapor pressure at 60°F are given as **130 lb/lb-mol** and **6.50E-03 psia**, respectively.

Step 3 – Select and record the saturation factor. The saturation factor is a function of the load method employed. Knowing that this fuel was loaded into non-road equipment from a POL tank, it may be assumed that the fuel was splash loaded without vapor balance. This gives a saturation factor of **1.45**.

Step 4 – Calculate emissions. Using the data from the previous steps and Equation 6-1, the total VOCs are calculated as follows:

$$E(VOC) = Q \times \frac{1}{1000} \times 12.46 \times \frac{S \times P \times M}{T} \times \left\{ 1 - \left[\left(\frac{Cap}{100} \right) \times \left(\frac{CE}{100} \right) \right] \right\}$$

For Gasoline:

$$E(VOC) = 150,000 \frac{\cancel{gal}}{yr} \times \frac{1}{1000} \left(\frac{10^3 \cancel{gal}}{\cancel{gal}} \right) \times 12.46 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ 10^3 \cancel{gal}} \right) \times \frac{1.45 \times 5.20 (psia) \times 66 \left(\frac{lb}{lb-mol} \right)}{520.67^{\circ}R} \left\{ 1 - \left[\left(\frac{0\%}{100\%} \right) \times \left(\frac{0\%}{100\%} \right) \right] \right\}$$

$$E(VOC) = 150 \left(\frac{10^3 \cancel{gal}}{yr} \right) \times 12.46 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ 10^3 \cancel{gal}} \right) \times \frac{1.45 \times 5.20 (psia) \times 66 \left(\frac{lb}{lb-mol} \right)}{520.67^{\circ}R} \{1\}$$

$$E(VOC) = 1869 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ yr} \right) \times 0.956 \left(\frac{psia \ lb}{^{\circ}R \text{ lb-mol}} \right) = \mathbf{1,786.8 \frac{lb}{yr}}$$

For Diesel:

$$E(VOC) = 85,000 \frac{\cancel{gal}}{yr} \times \frac{1}{1000} \left(\frac{10^3 \cancel{gal}}{\cancel{gal}} \right) \times 12.46 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ 10^3 \cancel{gal}} \right) \times \frac{1.45 \times 0.0065 (psia) \times 130 \left(\frac{lb}{lb-mol} \right)}{520.67^{\circ}R} \left\{ 1 - \left[\left(\frac{0\%}{100\%} \right) \times \left(\frac{0\%}{100\%} \right) \right] \right\}$$

$$E(VOC) = 85 \left(\frac{10^3 \cancel{gal}}{yr} \right) \times 12.46 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ 10^3 \cancel{gal}} \right) \times \frac{1.45 \times 0.0065 (psia) \times 130 \left(\frac{lb}{lb-mol} \right)}{520.67^{\circ}R} \{1\}$$

$$E(VOC) = 1059.1 \left(\frac{^{\circ}R \text{ lb-mol}}{psia \ yr} \right) \times 0.002 \left(\frac{psia \ lb}{^{\circ}R \text{ lb-mol}} \right) = \mathbf{2.12 \frac{lb}{yr}}$$

Step 5 – Record xylene weight percent. Table 6-6 states that the vapor weight percent xylene in gasoline and diesel fuel is **0.205%** and **6.06%** respectively.

Step 6 – Calculate xylene emissions. Using the VOC emissions for gasoline and diesel fuel calculated in Step 4 and the vapor weight percent xylene in each fuel as recorded in Step 5, the total xylene emissions are calculated using Equation 6-3 as shown:

$$E(HAP) = E(VOC) \times \frac{WP(HAP)}{100}$$

For Gasoline:

$$E(Xylene) = 1786.8 \frac{lb}{yr} \times \frac{.205\%}{100\%}$$

$$E(Xylene) = 1786.8 \frac{lb}{yr} \times 0.00205 = \mathbf{3.66 \frac{lb}{yr}}$$

For Diesel:

$$E(Xylene) = 2.12 \frac{lb}{yr} \times \frac{6.06\%}{100\%}$$

$$E(Xylene) = 2.12 \frac{lb}{yr} \times 0.0606 = \mathbf{0.13 \frac{lb}{yr}}$$

Step 7 – Calculate total VOC emissions. The total VOC emissions from fuel dispensing are the sum of evaporative emissions from each fuel calculated in Step 4.

$$E(VOC) = \sum_{i=1}^n [E(VOC)_i]$$

$$E(VOC) = \left(1786.8 \frac{lb}{yr} + 2.12 \frac{lb}{yr} \right)$$

$$\boxed{E(VOC) = \mathbf{1,788.9 \frac{lb}{yr}}}$$

Step 8 – Calculate total xylene emissions. The total xylene emissions from fuel dispensing are the sum of evaporative emissions from each fuel calculated in Step 6.

$$E(HAP) = \sum_{i=1}^n [E(HAP)_i]$$

$$E(Xylene) = \left(3.66 \frac{lb}{yr} + 0.13 \frac{lb}{yr} \right)$$

$$E(Xylene) = 3.79 \frac{lb}{yr}$$

6.6.2 Problem 2 – Emission Factor Method

Using the same throughput for gasoline and diesel as given in Problem 1, re-calculate the VOC emissions using the EF method.

Step 1 – Select and record appropriate EF. Again, since the fuel was loaded into non-road equipment, the loading method is assumed to be splash loading without vapor balance. The EFs for gasoline and diesel are **12** and **0.03 lb/10³ gal**, respectively.

Step 2 – Calculate VOC emissions. Using Equation 6-2 and the EFs as recorded in Step 1, the total VOCs emitted are calculated as follows:

$$E(VOC) = Q \times \frac{1}{1000} \times EF(VOC) \times \left\{ 1 - \left[\left(\frac{Cap}{100} \right) \times \left(\frac{CE}{100} \right) \right] \right\}$$

For Gasoline:

$$E(VOC) = 150,000 \frac{gal}{yr} \times \frac{1}{1000} \left(\frac{10^3 gal}{gal} \right) \times 12 \frac{lb}{10^3 gal} \times \left\{ 1 - \left[\left(\frac{0\%}{100\%} \right) \times \left(\frac{0\%}{100\%} \right) \right] \right\}$$

$$E(VOC) = 150 \frac{10^3 gal}{yr} \times 12 \frac{lb}{10^3 gal} \times \{1\} = 1,800 \frac{lb}{yr}$$

For Diesel:

$$E(VOC) = 85,000 \frac{gal}{yr} \times \frac{1}{1000} \left(\frac{10^3 gal}{gal} \right) \times 0.03 \frac{lb}{10^3 gal} \times \left\{ 1 - \left[\left(\frac{0\%}{100\%} \right) \times \left(\frac{0\%}{100\%} \right) \right] \right\}$$

$$E(VOC) = 85 \frac{10^3 gal}{yr} \times 0.03 \frac{lb}{10^3 gal} \times \{1\} = 2.55 \frac{lb}{yr}$$

Step 3 – Sum the VOC emissions. Adding the calculated emissions from Step 2, the total VOCs, as determined by the EF method is calculated as follows:

$$E(VOC) = \sum_{i=1}^n [E(VOC)_i]$$

$$E(VOC) = \left(1800 \frac{lb}{yr} + 2.55 \frac{lb}{yr} \right)$$

$$E(VOC) = 1,802.55 \frac{lb}{yr}$$

108883	Toluene	75014	Vinyl Chloride	---	Lead Compounds
95807	2,4-Toluene Diamine	75354	Vinylidene Chloride	---	Manganese Compounds
584849	2,4-Toluene Diisocyanate	1330207	Xylenes	---	Mercury Compounds
95534	o-Toluidine	95476	o-Xylene	---	Fine Mineral Fibers ³
8001352	Toxaphene	108383	m-Xylene	---	Nickel Compounds
120821	1,2,4-Trichlorobenzene	106423	p-Xylene	---	Polycyclic Organic Matter ⁴
79005	1,1,2-Trichloroethane	---	Antimony Compounds	---	Radionuclides (including Radon) ⁵
79016	Trichloroethylene	---	Arsenic Compounds	---	Selenium Compounds

1. X'CN where X=H' or any other group where a formal dissociation may occur. For example, KCN or Ca(CN)₂.
2. Includes mono- and di-ethers of ethylene glycol, diethylene glycol, and triethylene glycol R-(OCH₂CH₂)-OR', where:
n = 1, 2, or 3;
R = alkyl C7 or less; or R = phenyl or alkyl-substituted phenyl;
R' = H or alkyl C7 or less; or OR' consisting of carboxylic acid ester, sulfate, phosphate, nitrate, or sulfonate.
3. Includes mineral fiber emissions from facilities manufacturing or processing glass, rock, or slag fibers (or other mineral derived fibers) of average diameter 1 micrometer or less.
4. Includes organic compounds with more than one benzene ring, and which have a boiling point greater than or equal to 100°C.
5. A type of atom which spontaneously undergoes radioactive decay.
